Hence, if there were any number of neutrons in the Sun now, there would be practicelly none a thou-andth of a sevond afterward We could invoke them, and the reactions in which they take part, as permanent sources of energy only if "new" neutrons were continually being produced, inside a star, by some sort of reaction between chaiged nuclei. To anticipate a bit, it may be said here that the possibilities of such processes have been exhaustively explored by experts, only to find that they would occur, if at all, so very rarely as to have no practical effect

For the source of stellar energy, we must therefore look to reactions between charged atomic nuclei. Here a notably successful theory has been developed by Professor Bethe of Cornell, along lines resulting from the recent work of Gamow and others, and the ponenet theory which Alkinson suggested several years ago, before neutrons had been discovered and while nuclear physics was still too young to permit us to follow out the various processes in detail. But again space fails, and our story must be "continued in our next."—Princeton. University. Observators, April 5, 1999.

THEY NEVER SAYNO'

"Prop" Men Furnish the Thousands of Odd Items
That Make Motion Pictures More Realistic

By ANDREW R. BOONE

"M EMO to prop department On Stage Four, nine o'clock Thursday morning, one Statue of Liberty, carved out of ice; double for Charlie McCarthy; mouse complete with hole, one blue snake dressed like a cobra, dummy camera, 100 rubber arrows."

Iving Sindler, veteran Hollywood property suzard, read the order, whostled softly and set to work Instructions speed to assistants, but he took over the most exacting job himself. Bending alone over a huge cake of a nig a Los Angeles cold storage plant, he worked through the night and next morning at sumup packed the little statue in heavy burlap bags, surrounded them with dry ice and drove arross the city to the studio. When the testing the principals were ready for the scene in "The Cowboy and the Lady," Sindler set the statue on a base of mashed postores, which doubled for see cream, and placed it in front of the eamera.

Sindler is one of those unknown wards of the screen, the property men who must have within reach every manner of thing, from crooked dice to synthetic blood, or be able to find or make overnight whatever the director demands, no matter how outlandshi it may be or difficult to produce. Hems numbering in the thousands are constantly required.

Hollywood's property creators never know what contraptions may be demanded next. Early one Sunday, a director decided he must have a "prop" mocking bird for several closeup scenes. Not only did he order it delivered Monday morning, but the little bord must be able to nove its head and beak as though in song, flap its wings, first its all and rufflethe feathers on the neck. One day for the job Y et 24 hours later a synthetic mocking bird stared back at the camera, its lifelike movements created by invisible pano wires running up through the body to the various parts.

In modern motion pictures, the property man has become an integral part of the production. He is responsible for all the furniture, furnishings, and things used or carried by players. If a gentleman public a handserthede from his pocket for a specified piece of business, that handkerchief becomes a "prop," and no longer is part of his wardrobe. A property man refolds it.

Were you to visit the property depart-

ment of any major studie, you would find the most amazing collection of "things" ever brought together. Cigar store indians rule clibwow with a repliea of the Crand Llama of Tibet Machine guns which once fired across. No Man's Land in the World Wai, revolvers made of rubler, crooked diee, and "haved" roullette wheels. Everything ever used once in a

Many other things are not what they seem in the moves Fruits and vegetables for instance, funer ware, glasses, pictures on walls, and windows. Not only must the property man keep ample supplies on hand for eating sequences; its up to him to preserve them through long, hot days under the brilliant lights. He sulface lettuce to keep it fresh and stiff, sprays fruit to discourage flues, changes the water on cut flowers every two hours.

THESE jacks-of-all-trades also assist the camera man by kiling highighis Instant-dryng liquid wax and purty kill reflections from glass-covered pictures And between sense involving glass doors or windows, the property man pastes long strps of black paper on the glass, to warn roving actors and technicians against walking into trouble.

Should you look over the shoulder of a property man into his case of propsyou of find an amazing collection of knick-knacks. Labels, theater tickets, husmoszards, bank checks from all countres, ink, manicuring servors, harmonicas, candy, slugs to serve as money, blood (glycerine and carmine powder), knepads for falls, fuller's earth to make dust, airline and railroad tickets, candles, and needles are only part of the long list.

Most unusual, perhaps, of all demands on the property men was an order for an acre of cogon grass weed with which to dress a tropical scene for "The Last Frontier." None was available in the United States, and the U. S. Department of Agriculture refused permission to import the plant. An ingenious handler of props solved the problem by securing permission to have five pounds of seed flown in from the Philippine Islands by Chipper plane, on the strength of his guarantee to keep the pernicious weeds cut before they came to seed. And he had to destroy the plants by burning when the picture was completed.

Above: Property men scoured Los Angeles' and San Francisco's Chinatowns for utensils and decorations seen in these Chinese junks, which floated on an artificial lake

Below: On one large outdoor set, 28 large paim trees were included in the property order. One of the trees is shown here being carried to location by a small boist

Left: A dummy camera, a sponge rubber microphone, and part of an order for one hundred rubber tipped arrows. All were turned out in a week by one property man

Right: Final adjustments being made on a machine gun just prior to a movie battle. The property department can supply any type of gun at a moment's notice

Right: A portable cabinet. Hundreds of items must be furnished by the property department for each picture

// **

A miniature Statue of Liberty was carved in ice for a dinner party scene in a recent picture. Wooden "stand-in" is at right

Below: Often for larger pictures, property men rehearse their jobs models. The models may or may not be used in the actual filr

MONTHLY DIGEST

FOOD IN A BALLOON

THE latest transparent food wrap is rub ber, and it has fulfilled its principal pinpose long before it reaches the retailers' shelves, with its sales appeal 'purely com-cidental," according to the Industrial Bulletin of Arthur D Little, Inc.

The name Cryovac will be recognizable to our classical race of food venders as nossibly meaning "cold and empty" Such an unorthodox trade name is descriptive of the

Vacuum packing --in a balloon

history of the new wrap before it is put on sale. In its original form it resembles a deflated, wide mouthed toy balloon. It is blown up, however, by stretching the wide mouth over a frame and drawing a vacuum around the outside. It thus takes the shape of the cylindrical container into which it has been drawn and the chilled sides of the container "freeze" it into the larger size Into such an open-end package is dropped a brother, a vacuum hose removes the inside air and draws the wrap close to the contents, then the neck of the balloon is twisted and clamped to make the whole vacuum pack air-tight Then comes the trick the package is immersed in warm water to "thaw" il balloon, it attempts to shrink to its original size, and stretches to a taut, transparent wrap around the plump chicken

Various potential advantages for such a food container are obvious, and Dewey and

Contributing Editors ALEXANDER KLEMIN

In charge, Daniel Guggenheim School of Aeronautus, New York University

D H. KILLEFFER Chemical Engineer

Almy claim to have realized many of them without most of the possible objections. A special latex rubber was necessary, with no sulfur. Special equipment was designed to reduce the handling time in packaging to a point well below that for many other wrap-Formulas and production technique devel oped in the manufacture of latex sounding balloons were required for the necessary low cost, strength, and so forth. Incidentally, in the chilled, expanded form, the rubber has surprisingly great strength. Most of the ad vantages claimed are due to the climination of an or to the complete moisture tightness Pork products, for example, are said not to develop rancidity in the fat, chickens to show no "freezer burn," the bane of low temperature preservation of poultry Prevention of moisture loss not only preserves the original weight, but reduces frosting of cool ing coils in the refrigerating units, and in creases their freezing efficiency

Bags for poultry are designed as one trip containers to be removed by the consumer Larger bags are intended for the storage of scasonal surpluses of green hams, pork loins, and the like, which are temporarily frozen and released for the market as needed For these nurposes, the latex bags can be washed shrunk, and reused several times. The largest hags are being designed for use with quarters of beef, yeal, and lamb carcasses, and are expected to find their principal market in the export field A bag for a 350-pound ide of beef is said to be a practical possibility

RUBBER LUBRICANT

MANUERINE has been proved to be superior to mineral oil lubricants for rubber tubes and other rubber articles for surgical use by a long series of severe tests Comparison between mineral oil and glycerine was made by coating tubes with each of these fluids, washing with soap solution

Conducted by F. D. Mc H U G H after five minutes, rinsing with water and finally boding five minutes to sterible them Rubber tubes lubricated with oil were un fit for use after 37 such cycles. After 200 boilings, those lubricated with glycerine were still firm and usable. The Inbricating action of each is satisfactory -D H K

PILOT VALVE

NEW industrial development by A Schrader & Son, known as the Pilot alve, is designed to give a delayed or prolonged blast of air for ejecting work from a press, after the ram has stopped its upward stion, It is especially useful on manually fed presses using overhead knockout or compound dies

The duration of the air blast may be regu lated by a simple serew adjustment on the valve. It is easy to service and saves money by conserving air and climinating the necessity of interchanging machine parts to achieve the results of a timed blast of air With yent closed, it may be used as an air control valve on any mechanism

TENSION WRENCH WITH FLASH SIGNAL

IN the assembly of many products, and particularly in the automobile industry, it is often necessary to tighten nuts and bolts to a uniform tension Wienches with needle gages and others which produce a click when a certain tension is reached have been used in the past, but both types have their disadvantages in dark or noisy corners of factories. The Blackhawk Manu facturing Company solves this problem with a wrench called the Torkflash, which flashe-

is applied to the handle of this new wrench, a signal light flash

a signal light when the pre-set tension is

No mathematics is necessary to operate this wreach as the required tension is easily set by the five-in-one scale which slips over the cylinder enclosing the flash-light as-embly at the base of the handle grp. This cylinder is rotated by finger pressure to show desired scale.

Torkfash has been tested at a capacity raiing of 1400 inch-pounds for 87,000 mechanical pulls without affecting accuracy or strength of the wrench up to that point. Heed at the usual range of 800 inch-pounds, it has been tested over 180,000 times and full accuracy has continued after that point.

ICE-COOLED MACHINE

N EWEST use for dry ice is as a coolant for machine guns. A detachable jackst, filled with dry ice and alspiped over the barrel, keeps the gun continuously could The scheme enables fighting planes and hombers to carry fewer guns, yet to maintain continuous fire.

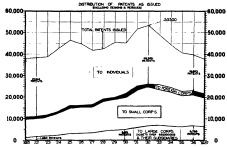

To Develop a LIFETIME

WITH child sized machines, sountists of the Fisk Tire Company are working in a miniature rubber plant to perfect the tire of the future that will carry automobiles along super-highways at 100 miles per hour

The miniature plant duplicates in every detail the gigantic factory machines used in standard manufacture. There are buss of compounds, mills and calenders for mixing tubber, a series of videanizers and preservability of the series of the series of the series are used in standard of pounds. A laboratory rubber batch is one pound; a factory batch, 750 pounds. The small mill is 12 inches wide, the standard mill, series of the series o

Purpose of the miniature plant is to facilitate research work, speed operations by working with small quantities, and climinate unnecessary waste.

Today these scientists are looking toward 150. The future tire, they say, will be lighter and tougher, with greatly improved safety features. The carcass will be stronger to stand greater temperatures of high-speed operation. With decreased weight through

An illuminating graph from the Journal of the Patent Office Society, which shows the total number of patents issued during each year, from 1921 through 1937. The distribution of these patents between individuals and corporations is particularly striking. It will be noted that, despite the impression that large corporations are obtaining the prependerance of patents issued doaty, their percentage is relatively small in comparison with the number of patents issued to small progressive cosporations as well as to individual memtors

redistribution of materials and through in proved materials, greater flexibility will be secured, which in turn will provide better riding and we aring qualities. Treads will be tougher to stand up under increased mileage

Eventually, they say, a tire will be made to last the lifetime of the car. In the meanime, when automobiles are ready to ride express highways, tires to carry them will be waiting—tires that were diveloped on these bally may hipes.

REJUVENATION ATTEMPTS Do Not Change Length

of Life

THE length of a person's life is set by a hiereditary time-clock or power of hiving that is in him when he is born, Prof. A J. Carlson of the University of Chicago recently told members of the American College of

Physicians
Contrary to the pseudo-science of rejuvenation, the sex glands are apparently not one of the links that determine the life span of the individual They only determine the level and duration of the reproductive period of life. Man and animals, Prof. Carlson said, would still grow old, grow feelbe, and the, presumably at the time appointed by the herdinary time-clock, even if they had no infectious diseases, at the best possible diet, lived and worked under doal conditions, and did just exactly the right amount of mortal and physical work.

How work may affect the life span is largely an unwritten chapter, Prof. Carlson said. No work at all seems to lead to fatness and degeneration. Excessive physical work can apparently cause degeneration by exhaustion—Struce Settine.

BENZOATES PRESERVE FISH

DIPPING fish fillers in a very dilute solution of mixtures of henzoc and and benzoates in salt brine prolongs the storage life considerably beyond that of untreated fillers. About 0.3 percent is the concentration of henzoates in the dipping solution A dup of 30 seconds to two minutes

The miniature rubber mill, left, being used in tire development, compared with a full-size mill, right

Above: The Tell-Tale control panel and. right, the sirplane parts that are controlled from the panel

affects only the surface of the fillet and leaves on it only about 10 percent as much benzoate as that used in the preservation of apple ender. The same treatment has proved effective with crah and lobster meat. Food laws require that fish so treated be labeled to indicate the presence of henzoates.— $D\ H\ K$

PAINT FOR TIRES

RECOGNIZING the present upward trend of demand for white sidewall trees. The B. F. Goodrich Company announces a new thite sidewall tree paint applicable for renewing white sidewall tree for for making present black sidewalls white.

Made with a rubber base, the new paint is self vulcanizing, is clastic and thus flexes with the tire and will not crack or chip. This new type paint is applied with a brush, dires quickly and can be washed with soap and water without affecting its original whiteness.

TELL-TALE

THE new Cuttes-Wright CW-20, new neuron completion, should be a fine, efficient, and aphendedly equipped transport. There is one mode device to be incorporated in it which discrete particular attention. Thus is the "Tell-Talle," developed to increase safety of operation and to decrease pilot largue by simplifying the task of control. In some respects the Tell-Talle is similar to the indicating, ugual systems used by the rativosk and the electrical power industry to warn of danger or improper operation.

A panel of lights is placed on the instrument board. These lights are electrically connected to various vital objectating parts of the plane, as indicated in one of the illustrations. The warning panel itself is shown in another illustration.

If the pilot wishes to land, he simply presses one of the ten pre-selector switches erated wind-tunnel have resulted in an airfoil and hinge arrangement for the aileron which assures ice-free operation of this vital control. The carbureter is non-icing, and there are both pneumatic and liquid de-icers on the wings and tail

We hope to give a fuller description of the new craft when its flight tests have been completed. Enough has been said here to indicate that our aeronautical engineers are fully alert to the need of greater safety for our arribures -A. K.

ANNUAL REPORT OF

THE complete annual report of the Na tonal Advancy Commutes for Aconassics contains dozens of deeply technical reports, and hindreds of printed pages. A summary of the guant volume is sent in advance to the Congress of the United States. It is interesting to pick out from this summary the results of the most significant research work, as an indication of the path momentum constants.

A better slotted flap has become available,

marked "Land" Lights immediately show on the Tell-Tale panel to indicate what adjustments are necessary. As the landing geris lowered, the corresponding light goes out As landing flaps and elevators are operated, their corresponding lights disappear. When the entire panel is dark, the pilot knows that it is safe to land.

If the pre-selector switch is directed to the right or left engine, lights immediately appear to warm of improper operating conditions as regards fuel pressure, oil temperature, head temperature, oil pressure, and other vital elements of engine operation Other headings on the Tell-Tale speak for themselves.

Bendes the Tell-Tale, many interesting features have been incorporated in the CF-20 to reduce pilot fatigue and hence the possibility of accident. Thus, large, hubless, spokeless wherels on all instruments assure better vision of the various disla: There is a angle-movement control lever for operating flaps and landing gear. Radio systems are duplicated. The landing gear retracts in five to ass seconds, can be lowered in three secveright routs upon it. The Icing heard has been specially considered. Test in a refriswhich gives such a high lift capacity that landing apeed is reduced more than ever before. The new type of flap increases lift without correspondingly increasing drag. Hence there should follow not only improved landing speed, but also improvement in take-off. A "Venetian Blind" type of flap has also been investigated, but details are not yet forthcoming.

There has been much research on the "tricyele" landing gear, also known as the nosewheel landing gear. The tricyele landing gear has been widely adopted by constructors, but has a tendency to "shimmying." Various experiments have been made to diminish such shimmying.

Radiators for liquid-cooled engines should no longer be of the external type which produce so much drag. If the radiator is placed within a carefully designed duct in the wing, much of the drag disappears.

In the refrigerated wind tunnel it was found that ice formation on the leading edge of the wing decreased the maximum lift coefficient from 1.32 to 0.80, and increased the drag by 90 percent. This is, unfortunately, mathematical confirmation of the serious hazards of ice formation, particularly in hastening the stall of the sirplane.

In its study of engines, the Committee has confirmed by tests what practical designers have long held-that the two-stroke cycle is most attractive for the aircraft Diesel .- A. K.

MAIL BY AUTOGIRO

R UMORS have come true, and Eastern Autogiro Corporation a wingless 'giro which will be used by the transport company in executing its United States mail contract covering the six-mile ferry route from the Central Airport, Camden, New Jersey, to the roof of the Philadelphia general post office.

The Kellett 'giro is a one-place ship, with a large mail compartment, and will carry all the necessary instruments for blind flying and the exacting service of roof landing The new craft is a derivative of the military 'giros which have done such excellent work with the Army Air Corps. High speed will

Mail-carrying 'giro

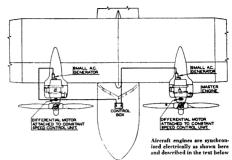

be 125 miles an hour, with low speed less than 25 miles an hour. The 'giro will land without forward roll and take off in less than 80 yards in still air. Specifications of the ship are span, 40 feet; useful load, 620 pounds, weight empty, 1630 pounds, pay load, 150 pounds; gross weight, 2250 pounds; fuel, 30 gallons; service ceiling, 14,000 feet; cruising range, 200 miles .-- 4 J

SYNCHRONIZING AIRCRAFT ENGINES

WHEN the motors of a multi-engined airplane are out of synchronism, an annoying "beat" is produced. For example, a difference of only 20 revolutions per minute between two engines will cause a distinct "beat" every three seconds. Since it is difficult to read a tachometer to within 20 revolutions per minute, attempts by the pilot to synchronize the engines are difficult and tedious. Moreover, even after the engines have been brought to the same speed by manual control, rough air or variations in operating conditions may throw them out of phase, to the renewed annoyance of the passengers.

Hamilton Standard Propellers engineers have, therefore, sought to secure automatic synchronization, and have fully succeeded by a system which is both ingenious and simple in principle. When the engines are operating at approximately the same speed, the pilot merely flips a switch; the synchronizer then takes control and brings the engines to exactly the same speed and keeps them

A combination of mechanical and elec-A commination of mechanical and elec-trical principles is employed in the syn-chronizer. The actual change in speed is accomplished mechanically through adjust-ment of the constant-speed control on a par-

ticular engine, by increase or decrease of the propeller pitch But the actual adjustment of the propeller control is effected electrically and automatically by a small differential three-phase motor attached directly

to the propeller control.

The principle of operation of the differential motor is that it will not rotate when the frequency of the power supplied to one of its windings is the same as the frequency supplied to the other winding Power for one winding is supplied from a small alternating-current generator driven by one engine Power to the other winding comes from another alternating-current generator driven from the "master engine". If the speed of any engine differs by as little as a single revolution per minute from the speed of the master engine, a difference of phase is created in the windings of the differential motor, and the rotor is set into motion, changing propeller pitch until all difference has disappeared

A very important feature of the differential motor is that its speed of rotation is directly proportional to the magnitude of the differences in frequency Thus, as the engine approaches the speed of the master engine, the corrective action becomes slower Hence there is no tendency to over-shoot the mark or to produce hunting.

Manual adjustment may be obtained at any time by switching off the synchronizer, but pilots naturally prefer the automatic system of operation, and the new device has been enthusiastically received by pilots and airline operators in general.-A K.

ANALYSIS OF LANDING AND TAKE-OFF

AN important question in transport operanot safe to operate certain transport craft in and out of certain airports?" To determine proper lengths of runways and the correct height and location of obstacles to approach or get-away, reliable information of landing and take-off characteristics under service conditions is necessary. Speaking before the Aeronautical Section of the National Safety Council, Major A. B. McMullan, of the Civil Aeronautics Authority, described a photo-graphic system which has been developed

by the Eastman Kodak Company for obtain-

ing such vital information.

The essential equipment consists of four spring-driven motion-picture cameras withelectrically operated single-frame releases. An electrical release mechanism is employed which gives absolutely correct timing. In practice, two pairs of cameras and two electrical controls are used. One pair of cameras is set on a short base of 60 feet, the other on a long base of 300 feet. With appropriate bases, markers, and so on, the airplane can be kept in view of the cameras throughout the take-off or landing process. Coordination of the films, timing devices, and so on, together with a projector on which the images produced by the two cameras of a pair are projected, and which is provided with reference markers, enables complete space triangulation to be carried out A species of photographic surveying is thus accomplished The final result is that a record is obtained of the exact position of the plane in horizontal and vertical distance at any instant of time. The value of such data is obvious -A.K.

START-STOP

AMERICA operates approximately 16,000 passenger trains, and omewhere in the land a train is either starting or ending a trip every five seconds.

ALCOHOL HAIR TONICS PLUS MASSAGE

W/HEN alcoholic preparations are used W on the scalp, vigorous brushing or massage should be used to stimulate the production of enough natural oil to offset any drying tendency they may have, according to the Journal of the American Medical As-

This statement appears in answer to a physician's query on accepted modes of treatment for falling hair.

Among the preparations suggested by the Journal for arresting acute loss of hair is a solution of cresol in alcohol. A milder form of treatment which has been the "favorite" of dermatologists for many years is a 1 percent solution of pilocarpine in 50-percent alcohol or bay rum, according to the Journal. This is said to have a specific stimulating effect on the growth of hair, possibly related

to its action on the vegetative nervous sys-

Other formulations given by the Journal are the following chloral hydrate, from 3 to 10 percent in 50-percent alcohol or bay rum; or mercury bichloride 0 3, tesoreinol monoacetate 6, spirit of formic acid 20, in bay rum or perfumed alcohol to make 120

MICHRES

DUT down the figure 10, then add 88 ciphers, and you will have the amount the voice is amplified by repeuters on a telephone call between New York and San Francisco.

MACHINE TO HARVEST SUGAR CANE

TATIVE sugar cane cutters in Hawaii will stand awestruck when the monster cane harvester shown in two of our illustra tions starts gobbling up stalks of cane like some starved mammoth which has chanced upon a field of particularly luscious grain

This giant- compare its tire (7 feet in diameter) with the truck-started its journey recently to Hawan where it will be put into operation by the Honolulu Sugar Plani-ers' Association Built as an experimental unit, the harvester will be "field-engineered". any changes proved necessary by operating trials will be made by means of the trick shown, which is a traveling fabricating shop fitted with Lincoln Electric Company are welding equipment, driven by power take off from the truck drive shaft

The sugar cane harvester was built for the Honolulu Sugar Planters' Association by R. G. LeTonrneau Inc., and has been in process of development for many months The idea for it give out of a discussion of cane harvesting problems between Hawanian cane growers and R G LeTourneau

The cane harvester will cut the cane just below the surface, yet high enough to avoid injury to the roots. As it cuts the cane, the machine will pick up the stalks, take them into its cutting compartment, cut them into pieces approximately a foot long, then carry the pieces by conveyor mechanism to trucks or wagons which will travel along beside the harvester

The engine installed in the harvester is a 160 horsepower Diesel built by Caterpillar The large generator mounted on the front of the engine is for the purpose of furnishing power to electric motors which drive the con ors and other operating mechanism

This huge piece of machinery is success fully operated by only one man

CONVERSATION TIMER

N business offices where numerous long distance calls are made or where over time is charged on local calls, it is often considered necessary to time any given conversation carefully to avoid extra charges. In

To time talk

such offices a small clock like device called the Phone O Meter would prove invaluable Operated by a clock escapement this meter may be set for any timing up to five minutes by merely turning the dial pointer by hand Set at the beginning of a telephone conver sation, it rings a hell a few seconds before the normal time is up

PAPER GLAZE FROM CORN

THE protein from corn is being used to THE protein from comes and composition for fine printing papers. This replaces casein from milk used in similar compositions -D. H K

BLIND TYPE PULL RIVET

NEW type of rivet has been developed to be used in places where there is a blind side, that is, where one can work from the outside wall only and where heating, hammering, or upsetting are impractical This new Hopkan blind rivet can be used

for assembling the finest thicknesses of sheet metals, often where it is impossible to use other fasteners and rivets. Also, it may be used for fastening woven materials- such as upholstering to wooden or steel frames-or where it is desired to fasten boards to steel or Rakelite

The male part of the rivet has a shank with a groove in it for pulling purposes. This is pulled through the slotted female part. The male and female are put through the structure from the outside with a pulling device. (Any standard puller can be adapted for use on the Hopkan blind fastener). The puller holds the female, while the male is pulled to its proper distination, at which time the shank of the male automatically breaks off. This leaves the hole evenly filled. and makes a smooth finish, regardless of the shape of the head

The rivet can be made from any type of teel, aluminum, or brass or other durable alloy The head can be made button, flat or hexagon, and the rivet can be made in any

CHEMICAL ELIMINATES PAINT ODORS

THE objectionable odor and eye smarting which accompany interior painting usu ally arise from the oils which the paint conturns rather than from the solutile solvents A new product, Santomask, added to the ngent will aliminate discomfort to the ownpants. One or two teaspoonfuls per gallon are all that is required, and the chemical will not affect the normal characteristics such as

diving time, durability, or color

The manufacturer, Monsanto Chemical
Company, claims that the new product will be especially advantageous for office buildings, hospitals, schools, horels, and homes buildings which frequently are occupied during redecoration and painting

EXPLOSION DAMAGE

AMAGE from one of America s major sources of destruction-dust explosion -can be materially reduced by scratchmy the outer surfaces of windows in factories where dust explosions are likely to occur, according to Hylton R Brown of the U. S. Bureau of Chemistry and Soils

Standard size panes, with a pair of diagonal scratches starting two inches from the edge and omitting a section two inches

Front and rear views of the new machine designed to harvest sugar cane

across in the center of the pane, will break at such low pressures that the exploding dists will not have a chance to knock down wills, he indicated Yet the window panes will be sufficiently strong to resist outside wind pressure.

Some such scheme is a necessary measure for "it is impactical to build walls strong enough to withstand the pressures produced," Mr Brown pointed out, He recommended swinging vents as the most satisfactory way of getting rid of the diagerous dist-explication pressures, but pointed out that such swinging window could be installed in existing buildings only at great extenses.

Unscored window glass, particularly of the "double-strength A quality" most widoused in factory construction, is much to strong to vent the force of an explosion successfully, he indicated. The window frame uself may go first when such a glass is used

Property damage in excess of \$15,000,000 and deaths in excess of 300 have been caused by dust explosions in the last two decades

Dividing a building with unpicreed walls was another of Mr Brown's suggestions. It would prevent the spread of the explosions Explosive dusts include a wide variety starch, grain, wood flour, sulfur, cork and others being among them. Science Service

THAT HIGHWAY WHITE

STRIPE

SOME time ago a nationwide search was conducted for the originator of the center traffic selecty time on highways, the "whitestage of the product of the conducted way." It has been also been as a ward N. Hines of Derrort, vice chairman of the Wayne County Board of County Board Commissioners and a prominior figure in highway and highway safety activities for main verse.

A plaque was presented to Mr. Hines to commemorate his great contribution to high way safety, a method now being used internationally

His origination of the center traffic stripe

Now comes Alexander L II Darragh, of Clicago, who submits a photograph of a section of old highway between Mexico City and Cuernavaca, Mexico, built under the

Traffic dividing stripe on a Mexiran road built some 400 years ago

Above. One of the sodium bombs compared with the tube in which it will be used. Right. Final stage in the production of the bombs. Filled with triple distilled sodium, they are ready to be sealed and removed

Spanish regime 350 or 400 years ago, and clearly showing that the "white stripe" was in use even then

This stone road, many sections of which are in service today, being used mainly by foot travelers and light animal-drawn vehicles, has a "built in" center line of lightcolored stones.

Mr Durragh took the photograph at a point where the old road inter-sects the new and modern highway to Mexico (ii). He whole contact from the theory of the "white center line" to the decision of the have been put in, even those days of pumparative antiquity, to prevent quarrely between those ancient traveless who wanted to be sure they got their half of the toad for

SORIUM ROMBS

GETTING a pinch of sodium into the sodium vapor lamp, the golden-orang lamp which is becoming increasingly common in highway lighting, is a complex problem, the solution of which involves the explosion of a "bomb" smaller than a marble

The sodium lamp consists of an evacuated tubular bulb with an electrode at each end. When the current is turned on, the sodium, showing as a mirror like deposit when the bulb is cold, is vaporized and becomes the current conductor, giving the bulb its characteristic golden-orangic colds.

The problem is to get the required amount of pure sodium—about 180 ounce—inside the vacuum tube without exposing the sodium to sir. A try bomb, a glass bulb containing pure sodium, does the trick, Making the ministure bomb is a complicated process in itself. Before being seeled within the ministure bomb, the sodium andergoes a triple distillation. Attached to the fourth vestee a triple distillation, Attached to the fourth vestee to the distilling system by slim necks, or capillary tubes, are the glass cases of the sodium of the solid problems. The state of the sodium of the solid problems is released into the system to force the sodium from the sected own into the bulbs. Heat

is then applied to the necks to seal off the bulbs and remove them.

After the sodium bomb has been placed in the ham been cacutated, a high frequency coil is placed around the tube. This coil induces heat in any metal within the tube, by a sort of 'wireless,' or tadio process. It causes the sodium inside to melt, to heat still further to the boiling point, and to explode its glass bome.

The sodium is thus deposited on the walls of the lamp. Its glass case is shartered by the explosion into countless pieces. Since the glass case of the bomb is at the most six thousandits of an inch thick, the shartered pieces are hardly more than dust, which can be left in the lamp.

Before the miniature bomb explosion method was developed in the General Electric Company's Research Laboratory, the sodium was distilled separately into each lamp.

ON MAKING FEATHER DUSTERS

Tills recovery and use of feathers has tong been an organized business, and vast quantities of them have heen diverted to various uses—including feather dusters in making dusters the feathers are drawn through a metal ring to regiment the quille. Light as they may be, the feathers have a protective structure of timy, tough scales that scratch and eventually wear out this metal ring. One manufacture found his rings worn so rapidly as to mean serious unisance and expense. In succession, various unisance and expense. In succession, various

harder metals were tried—several types of steels, then Stellite, then Carboloy. As none was entirely satisfactory, he asked for suggestions from an ingenious worker in metals.

The successful solution was an exact reversal of the direction in which previous attempts were made. Little is known of the ultimate nature of friction, and the term "hardness" is all but meaningless without a description of the manner of its measurement or the nature of the opposing forces. Hardness as measured by penetration of a steel sured by depth of groove under a diamond cutter. It is therefore difficult to predict wear or friction with unusual materials or conditions. The microscopic surface of feathers presents an unusual combination of abrasive properties of surface, composition, and shape. Rubbed against what the inventor called "brute hardness," minute particles of metal wore away, whereas lead, not rigid, but pliable, apparently flowed back and forth under the pressure of the feather surface Lead was proposed and pure lead rings now wear almost indefinitely -The Industrial Bulletin of Arthur D Little, Inc.

ELECTRICITY COST

THE electric current consumed during its lifetime by an ordinary 15-cent, 60-watt electric lamp costs at least ten times as much as the lamp itself. Hence, even a 1 percent increase in the efficiency of a lamp will make a sizeable difference in its ultimate cost.

PRE-CAST CONCRETE SHAPES

PITTSBURGH, the cuty that gave the world standardized structural steel, now has become the birthplace of standard precast concrete shapes, which simplify fire-proof construction and lower its cost through mass production.

Use of vibration, heat, and mass production methods are the three main features of the system of manufacturing Cemenstone, as the pre-cast material is known. Vibration while molding is said to produce a finer tex-

Abore: Pouring the mix at one end of the continuous production Cemenstone mill. Right: A few of the pre-cast concrete shapes that can be produced with the same equipment

ture and a stronger product. Heat is used to hasten the chemical reaction of the cement when it is brought in contact with the other maternals and water. It also is aud to induce uniform shrinkage and a product of a uniform light color. Mass productor has been made possible by the development of a system which permits rapid cycles of manifacture and the making of several shapes at one operation. The method of molding, curedges and corners so that they have the appearance of cut stone.

pearance of cut stone
Among the products which can be pro-

Designed to speed up sweeping of sidewalks and floors in industrial plants, the "Flying Data Pan," invention of R. C. Howell, a Clewlend industrial engineer, is powered by a one-horsepower motor and mounted on General Streamline Jumbo Jr., pneumatic tree. It runs at a speed of about three miles an hour and can present the proper of the properties of places and the properties of the prolenges as heard eggs, the sweeper can be manipulated to work within an inch and a half of a factory wall duced by this method are blocks for wall construction and channel-shaped, short-span alabs for floors and roofs, as well as longspan slabs, concrete plank, joists, brick, insulating tile, and veneering, also curbs, sidewalks, and fence posts.

The production equipment consists of a rigid steel frame over a curing chamber which produces a temperature of 160 degrees, Fahrenheit. A hopper, which fills the molds with concrete, maxed to a plastic state, rides on the top of the frame, together with wibators which agutate the mus. Steam from the curing trough keeps the molds constantly hot. After the concrete has hardened suffi-

ciently the products are lifted out in large groups and unloaded for aging under cover and in a constant temperature, to prevent unfavorable weather conditions from arresting the proper chemical reaction within the concrete.

COPPER CURES FUNGOUS DISEASES

COPPER, passed through the skin by electric current, is being successfully used in treating fungous infections of the hands and feet by physicians at Yale University Medical School

In the past, many remedies have been used to treat these painful and abhorrent akin infections without speciacular success. Of 37 patients treated at Yale by means of electric current, 26 have been discharged as cured. Some of them had severe infections of long duration, one for as long as 25 years. The average number of treatments given was

The afflicted person sits with his feet immerced in cannel pan and with the hands in other basins. When the infection is on the feet, the hands are immerced in salt solution and the feet in 02 percent copper sultion salt the feet in 02 percent copper sulfate solution. For infections of the hands the relations are reversed. The duration of the treatment is 20 minutes. Special apparatus has been devised to obviate the danger of electric shock.

Dr. Howard W. Haggard, Dr. Maurice J. Strauss and Leon A. Greenberg described the new treatment in a preliminary report in the Journal of the American Medical Association.—Science Service.

RUBBER-TO-METAL CEMENT

There has long been need for a cement which will stick many different kinds of materials, including rubber, to metals. Such a cement has been developed by the St. Louis Rubber Cement Company and is available in all sire packages from one ounce to 55 gallons. This product, which is celled Cripitic Cement, is easily applied, can be

made to be a quick or slow dryer, and to withstand any climatic conditions. The manifacturers claim that the longer it sets the more tensors it is

Criptite is made from a combination of tubber, selected gums, and chemicals. The result is a cement that "welds" rubber to metal, anti-squeaks to metal, rubber to enameled metal, felt to metal, blue wadding to metal, cardboard to metal, and linoleum to metal and concrete.

TUBE-WALL-SCOPE AND

TWO new procedures involving a recently eveloped instrument, the Tube-wall-cope, and a new application of the Magnafux method are now being used to inspect, during production, both the interior and exterior surfaces of every length of J & L Blue Ribbon seamless steel integral joint drill pape manufactured by the Jones & Laughlin Steel Corporation.

The Tube-wall-scope fills a long-felt need or an accurate, scennific method of inspecting the inside of tubular goods for defects which ecentually unglat result in pipe fail ures in the field. The Tube-wall-scope is a previous instrument reembling an exceptionally long telescope. It is equipped with an adjustable forem eyeptice at one end and a series of special benear, reflectors, and a series of special benear, reflectors, and a series of special benear the proported pilat at the special period of the proported pilat at the special period of the proported pilat at the special period of the proported pilat at the special period period pilat at the special period pi

the barrel serve to center the instrument in the pipe.

As the Tube-wall-scope magnifies the size of the image of a defect, an experienced inspector can quickly recognize any flaw as a possible source of failure and by calibrations on the instrument barrel can then read ily determine the location of a defect.

Every length of integral joint delli pipe move being produced by the company in also subjected to the Magnaffux test. This drill pipe elliminates the conventional type tool joint by having a forged upset tool joint integral with the pipe itself. The Magnaffux test is applied to the exterior of this forged upset to detect and wished to the ever the contract of the contract of the contract lates that will materially reduce the possbility of failures at the joint. This test consists of placing the pipe in a magnetic field and then sprinkling the pipe with a metallic powder or solution. Even though not otherwise visible, any defect will immediately become apparent as the red powder is attracted by magnetic action to a flaw and collects there.

THE KORT NOZZLE

An appendage which is in-talled perma neutry on the sterm of vessels to surtound the propeller as a sort of tube, and called the Kort mozle, is being rajing adopted for use on small vessels. The device, which is handled in the country by the Device Corporation, produces an additional effective thrust from the screw propeller without increasing the load. It is intered for use on well-designed vessels but is not for use on poorly designed ones. It has no moving parts, no evonsertion to moving parts, consumes an opener, and is physically as strong as the hull

The duty of the Kort nozzle is to control the direction and velocity of the water pass-

How the Kort nozzle drives a cylindrical column of water sternward, thus obtaining a "productive push"

ing to, through, and away from the propiller, with the further dusty of obtaining additional forward thrust through the control of the section value of the propiler "draw" on the hydrofoll sectioned ring. The underlying principles through which this mozile game is superior propilling efficiency are not undy technically attent too log to explain in debt of the propiler is to drive stermand a cylindrical column of water and from this propeller is contributionally a contribution of the propiler is of their setting with the propiler is drawn of water and from this propeller is acceptable public "is obtained by the propiler is of the setting the propiler is of the propiler is of the setting the propiler is of the propiler is of the setting the propiler is of the propiler is of the setting the propiler is of the propiler is of the setting the propiler is of the propiler is of the setting the propiler is of the propiler in the propiler is of the propiler in the propiler in the propiler is of the propiler in the propiler in the propiler is of the propiler in the propiler in the propiler is of the propiler in the propiler in the propiler is of the propiler in the p

cent and 25 percent may be expected at normal towing speeds. The case of the Motocoaster Jame of Gronnagen, Holland, will serve as an example. Trails assed in calm water over a measured mile without the Kort mozile gave a speed of 78 k nots with the engines developing 225 5 H P at 298 revolutions per minute while the Jame was consuming 3904 pounds of fuel per hour. After the application of a Kort nozile, on the same course and under similar sea conditions, the vessel attained a speed of 86 knots with the engines developing 219 8 H.P, at 322 revolutions per minute and consuming 80 pounds for the same course and under similar sea conditions, the same seal that the same and consuming 80 pounds of the same seal that the same seal

A NEW JOINT

A NEW clettra widing process, successfully adopted in a number of industrial plants, provides rand, automate making of steels, standers and automate making of steels, standers and other alloy steels. The "I'mommel" process use as an electrode a bare welding rod automatically fed, heard by the passage of an electric current from it to the work being welded. The end of the electrodic is constantly covered by a special granulated material which is automatically well of the work being welder.

The granulated material used is a highresistance conductor of electricity in the molten state, and hence makes possible the user of very high current densities which cause rapid generation of intense heat. It also acts as a heat invultant and concen-

trates the heat in a small welding zone. The molten portion floats as a longud blanket over the weld metal, protecting it from the atmosphere, and the actual welding takesplace beneath this liquid blanket, without widence of an arr, and without sparks, spatter, smoke, or flash. By using various combinations of amperage, voltage, and welding speed, the shape and the reinforcement of the weld can be varied and the depth of the fusion zone can be regulated as D. Lutle. Inc.

NEW LIFE PRESERVER

THE belt worn by the bathing gul in our illustration is the invention of G. J. Peterson of North Dakota, who spent almost four years in its perfection. It inflares and quickly becomes a life preserver in an emergency. The Swimaster, as it is called, has the appearance of a handsome swimming belt, uses ordinary Sparklet syphon cartridges swinable at all drig stores, and

There is nothing unusual in the appearance of the swimming belt shown at upper right, but it can be instantly inflated to act as a life preserver, as pictured above

can be used over and over again. A slight squeeze of the helt buckle inflates the Swimsster to a biovainty more than sufficient to float the heaviest person, even in hunting clothes, from 12 to 16 hours or more, in summing position!

Hunters and fishermen may wear the heli under clothing where it will remain incon spicuous and still operate efficiently

PENNIES SAVED

HOLSEWIVES balut of utilizing the bags in which sugar, from, rec, and other similar materials are delivered to them, the at last stimulated him makers to action. A new series of printing inske to be used to print labels on such bags gives impressions which are satisfactory so long as needed, but which can be readily washed out by the binus wife By using pigment inks with these removable ones, part of the design can be removable ones, part of the design can be will leave a stam in the cloth when washed out with soap and water—D. H. and

OLD MATHEMATICAL

PUZZLE STILL INTRIGUES

O NE of the great mysteries in the history of mathematics is known as Fermat's last theorem. In the year 1637, brilliant Pierre Fermat, great French mathematician,

wrote in the margin of an algebra book this statement:

"If n is a number greater than two, there are no whole numbers, a, b, and c such that a" plus b" equals c". I have found a truly wonderful proof which this margin is too small to contain."

Unfortunately, after Fermat's death in 1665, an examination of his papers showed that he never wrote out this "wonderful" proof And in so doing Fermat left a mystery

which probably every first rate mathematician since his time has puzzled over at least

Many of Fermat's mathematical followers spent entire lives on the problem and at least three large cash prizes (one in 1907 amounting to nearly \$25,000) have been offered for a solution to Fermat's moment of inspiration. Like some modern movie or eigarette contest these prizes produced a vertiable varianche of "obtionion," mostly from aniavalanche of "obtionion," mostly from aniaty of the prizes of the prizes of the prizes that the prizes of the prize of the prize of the Buern proved for values of a less than 617.

Reporting recently to the American Mathe

matical Society, Dr. J. Barkley Rosser of Cornell University described a method of treating a special, amplified form of Fermat's famous theorem so that many values of n can be handled at once. With this method he has proved this special case for all values of n less than 8,332,403.

This special form puts on the restriction that the number it must not divide a, b, or c. Previously Dickson, in 1998, had proved this case for numbers up to 7000 and, in 1925, Beeger did for numbers up to 19,000 By comparison Dr. Rosser's contribution is enormous—Screene Sertice.

ILLUMINATION

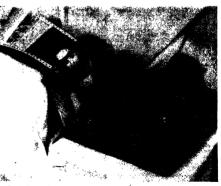

"SIGHT is precious," says the Swashington Water Power Company, Spokane. "It is estimated we use our eyes for severe visual lasks about 30 percent more than was common a generation ago—and many times more than a century ago."

FOR HOMEBUILT RADIO FACSIMILE RECEIVERS

THE anatous who likes to huld his some tadio receives can now add another interesting radio development to his accomplishments. He can secure the parts and build his own facsumle tadio printer Because of the great interest around by this latest development in radio, The Crody-Corporation has prepared a kir containing all the parts increasity to huld a Reads facsimle connection with his own radio receiver.

connection with his own radio receiver.

Facusinic radio printing is in its infancy
today just as radio tiself was 20 years ago,
and with the possibility of radio printing
coming into widespread use in homes and in
other places as yet untouched, the radio
amateur has a highly interesting field in
which to carry on his septements.

Facsimile recorder which can be constructed from an available kit of parts

The Crosley Reado radio printer is a divelopment of the Fisch nethod (See Section to the American, June, 1938) and is being used in many places throughout the country. The time probably is not far distant when audio facismile printers will constantly deliver an interesting stream of timely new times and pictures of news events, as well as other information, into homes and other places.

CONTROL FOR PEACH

ETIMENE debiloude, widely used in fungating grain, has powed more of feture in controlling peach bottes than many materials, now used, and in addition it is casy to apply with little danger of in may to the tree and is relatively charge Libbline diebilioride is emissified with war containing postals fish of soaps, and this emission is poured about the bases of the tree. The treatment can be given to trees of any age and can be applied at any season. D. II. A.

SEAR OFF STEEL SURFACE DEFECTS

F1.ASHING, searing flame is removing the archamed production of steel from the output to the watching of the finished product of a steel from the output to the watchings of the finished product. Data bottleneck was the stage known as bloom finishing, when the variate a defects in the steel had to be removed to meet customer dismands.

Flaming torches, burning oxygen and acrylein gas, are now searing of the oil side surface of gunt hillers in many steel mills of the land. They are replacing older methods which employed many men to clap off the defects with pneumatic choicle or lung machines—power-operated but mancontrolled—which did the same thing.

Flame scarfing is the name of the now mithod. The steel makers have been reluctant to talk much about it until it had achieved a success over an appreciable period of time, in full scale commercial production. They had been fooled, too many been solded to be a full period of the steel have solved the problem of bloom huvdung. But that trial period is now over and gins are replacing skeptical flowns on the faces of the nation's steel masters.

The Ln-De-Surface is the name of a flame scarfing device coming into increasingly wide use in steel plants. It takes its best position in the steel mill's otherwise continuous chain of production when it is placed in the blooming mill near the guard shears that cut off chunks of steel a foot in diameter and 10 or 12 feet long.

These chunks, the blooms, go through the fiame-cutting treatment, lose their surface defects and pass on to the rolling mills.

In actual operation the bloom passes into the unit and ris surface is pre-heated, to the point where it just begins to flow, in about two seconds. This is accomplished by multiple torch openings which may number as many as 28 orifices. Then, at the proper instant, along comes oxygen gas and sears off the outer surface to any depth desured up to a quarter of an inch.

In the de-surfacing unit the blooms move

WHERE SCIENCE ENDS HOSPITALITY BEGINS

The Waldorf, for example, is a magnificent scientific achievement, not only dependent on science when it was built, but continuously dependent on many sciences for the efficiency of its operation.

But every man of scientific turn of mind knowwhat we mean when we say that hospitality, in his own home no less than in the Waldorf, is something warm. Irving and human that survives scientific detachment

And it is that ability to preserve the human touch, in spite of all our clockwork schedules and efficiency, that gives the Waldorf its unique reputation for maintaining close, cordial and communicable contact-with its patrons.

Besides, this year, when you come to New York, you'll get so much science at THE FAIR, that it'll be a genuine relief each day to return to the hospitality of The Waldorf-Astoria!

Experimenters - Schools - Field Workers

An Accurate Balance at a Price Within the Reach of All

Sensitive to 2/50 gram Weighs up to 100 grams Compact-No loose parts Modern, durable construction Small convenient size Handsome streamline design Now permissible for auxiliary use in drug stores (N. Y. C. Serial B17.)

Never before a balance with all these exceptional features!

Funcit Quality— Made of tested materials. Its construction will appeal to laboratorica desting the bost equipment. The Bakelite cup is unaffected by practically any substance that can come in contact with it: the tool steel knife edge and agate bearing will give long life and accuracy.

Extreme Sensitivity—Welghs to one decimal point farther than the usual low-priced counter scales and serves nearly every laboratory purpose short of precise analysis. The capacity of 100 grams is ample for the delicate

weighings made in the usual course of teaching, organic avnthesis, experimental work, compounding, photographic work, etc.

Compact Convenient—Does not monopolize laboratory table. Placed on the desk of the busy technical executive, it will soon becomindispensable

Its small size makes it possible to carry it on inspection and testing trips at a distance from the laboratory It is small enough to be carried under the arm or in an overcoat

Graduated in either the Metrie System (grams) or the Apothecary's System (grains, drams and cunces) In ordering, please indicate which of these yes desire.

against the blast of oxygen flame at a rate which can be as high as 175 feet a minute. The oxygen velocity is low, in contrast to the high speed flame of the ordinary oxyacetylene cutting torch, and peels off the surface. The slag formed consists of about 80 percent iron and can be used over again to charge blast furnaces,-Copyright by Science Service.

PLASTICS

IN 1926, production of plastics in the United States was 10,000,000 pounds. A fast jump to 30,000,000 pounds was made by 1932, and an enormous increase to 162,000,000 pounds in 1937.

CALOMEL, VALUABLE

INSECTICIDE

DOSING cabbage maggets with calomel applied in a suspension around the young plants, as a dust, or as a coating on the seed, has distinct advantages over most other methods yet devised for combating this troublesome pest, according to Dr. Hugh Glasgow, entomologist at the N. Y. State Experiment Station at Geneva.

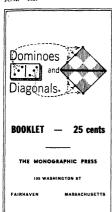

The insecticidal properties of calomel were discovered largely by accident a number of years ago in some tests at the Station in which all of the salts of mercury were included as a matter of routine, explains Dr. Glasgow. Such striking control of the root maggot was obtained on the calomel plat, however, that it was immediately made the subject of careful tests, with the result that it was found to have some decided advantages over corrosive sublimate, the standard treatment, although no more effective than the latter in controlling cabbage magget.

One of the chief advantages that calomel possesses is that there is little danger of injury to tender young plants from its use, whereas corrosive sublimate must be used in a fairly dilute solution and even then may cause injury to cauliflower and radish seedlings. Corrosive sublimate is also suspected of delaying the harvesting date of early cabbage and cauliflower. Because it can be used in heavier dosages, calomel generally does not need to be applied as often as corrosive sublimate.

Calomel may be applied in suspension in water, as in the case of corrosive sublimate, or at may be used as dust, or it may be applied directly to the seed at planting time. "In fact, any method that results in placing the calomel near the point where the eggs of the insect are normally deposited should result in satisfactory control of the root maggot," says Dr. Glasgow.

TONETTE: NEWEST. SIMPLEST MUSICAL INSTRUMENT

ALL his life, Zeigner Swanson liked to tink-er with flutes, to play them and to build them. It is said that flutes are as old as willow branches and a tool to cut them; and "Zig" has amassed a collection of them showing their evolution from hellow willow twigs sign to the Tonette.

Tonette is made in two parts

played upon it-favorite times, simple classus, popular melodies, and so on. And already considerable music has been specially arranged for it. The Tonette is made of Tente, an unbreakable plastic material. Its tone is really a cross between that of a clarinet and a flute Everything learned on the instrument carries over directly into the study of all other instruments. That is why music educators are adopting it as standard are hand equipment for young music students Its dollar price brings it within the reach of every child, and gives his parents an opportunity to see whether be has what it takes to learn to play-either for his own amusement or for any other purpose-before investing in a high priced instrument. It is also used by professional bands for novelty

One is a well-known product—methanol, or wood alcohol. Four others had not been previously discovered, although one of the group was described as theoretically possible by a German scientist. The properties of these new substances are such as to suggest their use as wood preservatives, fungicides, insecticedes, adhesives, solvents, and plastic materials.

The co-discoverers, Dr. E. C. Sherrard and Dr. E. Harris, describe the first new substance as paraprophykylobexanol, valuable as a solvent for organic gums and resins, and oils used in lacquirs. It has value as a preservative, and is about as repellent to

The second and third substances, described as 4-propyl, 1, 2 dihydroxycyclobea, and an 3 p hydroxycyclobexylpropanol, are thick liquids which become solid after standing a long while. Both may be made into plastic materials.

The fourth substance is crystalline and unnamed, as the discoverers have not yet determined the positions of the carbon, hydrogen, and oxygen atoms of which it is composed.

Because of its complex chemical nature, humon into natural form has baffed seem tasts. By submitting it to the hydrogenation process, the Forest Service securities changed its chimical nature so that it could be backen down into component parts. The hydrogenation process already is in use comnectably in making hard fast from vegetaand in getting phenomenal yields of gaodine and in getting phenomenal yields of gaodine and as only from natural performan-

In the laboratory tests the hydrogen atoms were added to a solution of puritied ligum by means of heat and pressure and the use of a catalyst—copper chromoun oxide—another chemical indicate graph reaction, yet taking no part in it. Under thus treatment the dury, brown ligum solution changed to a thick, strek, and coloriers fluid. The catalyst was removed by the use of a centrifuge, which works on the principle of a cream september of the control of the

99,9999 PERCENT

PURITY of metals is difficult to achieve, yet very important in research, alloy making, metal coating. Metallurgists have made lead 99,9999 percent pure.

FOLDING, LIGHT-WEIGHT

O NE of the latest developments in the marine accessory field is a new light-weight anchor fabricated from high strength Monel sheet. It is welded throughout, except where the arms and stock meet the shank. These joints are pinned so that the anchor can be folded for stowing when not in use.

Made m a variety of sizes from six pounds to 47 pounds in weight, the anchor is so designed that the 11-pound size will hold a boat 38 feet in length. With the conventional type of anchor, the general rule is to allow one to two pounds in anchor weight for each foot of boat length. This lightness of weight

is made possible by the design of the anchor, combined with the inherent strength of Monel.

Arms of the unit are set at right angles to the stock and are equipped with a set of sharp-pointed triangular flukes. These dig deeper and deeper as the pull of the craft is increased. The broad palms of the anchor, which will bury themselves completely in bottoms of clay or sand, provide an excep-

tionally strong grip. The anchor will not digitself out of the bottom until a direct upward pull is exerted on the line. Then the sharp-pointed flukes readily out their way out.

The light weight and small size of the anchor permit case of handling and reduce the danger of damage to the hull and tonsides Monel is highly resistant to corresion and the anchor will not rust in fresh or salt

water. This anchor was designed and is manufactured by the Youngstown Welding & Ingincering Company -Inco.

RUBBER-LIKE SUBSTANCE FROM DAIRY BY-PRODUCTS

SCIENTISTS of the U.S. Bureau of Dairy Industry have perfected a process for making a transparent rubber-like substance from lactic acid of whey that has many promising uses in various industrial opera-

Known to chemists as polymethylacrylate, the water-white semi-solid material is closely related to the so-called organic glass made synthetically and used for highway reflectors. It is softer and more flexible than organic glass, however, but is very tough and clastic.

Laboratory results obtained by Lee T Smith and H. V Claborn, chemists in the Bureau's Division of Dairy Research Laboratories, indicate that polymethylacrylate can be produced as cheaply from lactic acid by their method as it is now produced from ethylene or alcohol by the cyanhydrin process. The Bureau scientists believe the cheapness of their process will contribute to the increased use of lactic acid.

Because of their unique properties, polyacrylates are already in demand for various purposes. Their transparency, elasticity, toughness, ease of solubility, and stability to

sunlight and ultra-violet rays make them especially valuable in the preparation of lacquers, varnishes, inks, impregnating compounds, and cements.

All types of fabrics, paper, and other fibrous materials may be coated or impregnated with the polyacrylates to make them resistant to water, oil, and gases Fabrics with these characteristics are useful in making ship's sails, balloon cloth, and clothing for protection against poisonous gases, Treat-ed paper finds many uses, especially in the electrical industry.

Unlike the related organic glass material, polymethylacrylate alone is not suitable for making molded objects, either by the compression or injection method; but it can be combined with the organic glass to make a molding material superior to any of the original compounds.

RADIATION PYROMETER NEW radiation pyrometer which uses

A NEW radiation pyrometer whith the Ardometer, shown in the illustration, is being offered by The Bristol Company.

This instrument measures the surface temperature of hot objects or masses above 1000 degrees, Fahrenheit, when the Ardometer unit is sighted so that it picks up the

heat rays emitted. The temperature is recorded on a round- or strip-chart recorder or is indicated on a millivoltmeter pyrometer

The Ardometer has this important feature, it can be sighted directly on the object in the furnace and in this position it measures instantly the temperature of the object itself It follows with fidelity the temperature changes in the material on which it is sighted

LIQUID METAL POLISH

A FORMULA for a liquid metal polish developed in Germany is given as follows: Dissolve 8 parts of fatty acids in 15 parts of denatured alcohol, saponify with 4 parts of ammonia (sp gr. 091); add 2 parts of fatty alcohol sulfates; dissolve in 58 parts of benzine and stir the solution with 50 parts of fine Neuburger chalk.

trode vacuum tube and the effect of a magnetic field on a stream of electrons flowing through a vacuum, the engineers have built a trode 27 inches high and seven inches in diameter. It is similar to a standard radio tube except that it has two filaments and two grids on opposite sides of the plate so that the action is visible from both directions. This interesting tube is shown in one of our illustrations.

The surface of the plate is coated with fluorescent material, so that wherever elec-

The action of electrons in a vacuum tube is made visible in this demonstration model, as described

trons impinge on the plate, a green color shows, By changing the negative biasing voltage supplied to the grid, the stream of electrons to the plate can be varied from zero to the maximum of which the tube is eapable. A pattern on the face of the plate shows the area normally bombarded by electrons.

By placing a permanent magnet near the tube, the electron stream can be deflected by the magnetic field. The effect of the field on the electron stream can be seen plainly. This effect varies according to the way the magnet is applied to the tube.

The circuit used is similar to that in audio-amplifiers, A 60 cycle frequency is applied to the grid and the tube output is connected to a loud speaker. The loudness of the audio signal corresponds to the area for the green glow on the plate of the tube.

SULFAPYRIDINE IN PNEU-MONIA CASES

ALMOST all deaths from preumonia could han one be preumed if pneumona patients were given proper treatment on the first day they were taken sack. Dr. Perrin III. Long of Johns Hopkins School of Medicine recently lold members of the American College of Physicians. The millennium of no more pneumona deaths, which probably could be achieved by the new cheñical remedy, sublepyidine, will probably never be reached, Dr. Long said, because pneumonia patients do not see a doctor on the first day of sickness—in fact, usually not until they are desperately sick.

Serum would not be necessary in the treatment of pneumonia, Dr. Long said, if

sulfapyridine could be given the patient the first day of his illness. From the standboint of cost alone this would be a tremendous advantage. It costs about \$12 to treat a case of pneumonia by sulfapyridine but the cost of serum treatment is at least \$75. Serum is not always available, whereas suffapyridine is both available and effective in all types of pneumonia -- Science Service

RAILROADING'S LATEST CHAPTER

(Continued from page 361)

with a gear reduction unit. The turbine operates at a speed of 12,500 revolutions per minute and the diameter of the high pres sure totor is approximately 12 inches. The gear reduction unit has a ratio of about 10 to 1 A main traction generator composed of two armatures mounted on a common shaft and in a common frame is connected to the turbine. A three-phase alternator is mounted on the main generator shaft to supply alternating current used in the passenger car for lighting, air conditioning, and, on some trains, part of the heating load

A 50 callon self contained boiler of the water tube, forced cuculation type and using distilled water, furnishes 45,000 pounds of steam per hour for the turbine at 1500 pounds per square meh pressure and at a temperature of 920 degrees, Fahrenheit The steam is passed from a superheater through the high pressure turbine and then through the low pressure turbine. Then, instead of being exhausted as it is on the reciprocating steam engine, it goes from the low pressure turbine to a condenser and is returned to the boiler in the form of water to be used over and over again. Only small quantities of distilled water are required to make up loss es No more than a few tankfuls would be required by the steam electric locomotive on a coast to-coast run Compare this with the thirsty steam locomotive which may use as many as 200,000 gallons of water hauling a standard passenger train from Chicago to the Pacific Coast!

A 4000-gallon water tank of steel construction is installed in the nose of each cab of the steam-electric locomotive, this water being used for the most part in furnishing steam heat for the passenger cars

E LECTRIC energy from the turbine gen-erators is fed to six traction motors of the axle-mounted type on each cab. Each of the motors has a nominal rating of 600 horse power. In addition to furnishing driving power for the locomotive, these traction motors have another important function. They provide electric braking essentially the same athat used for regenerative braking in the straight electric locomotive. This dynamic braking, as it is called, is used both for service stops and for controlling the speed of the train on long down-grades. On the steamelectric locomotive, it will hold the train on a 2.2 percent down-grade at any speed desired. without the application of any brake shoes on either the locomotive or the train.

The motors become generators in the braking process and the power they generate is transmitted to a water-cooled resistor, a series of pipes through which water is forced to dissipate the heat generated during electric braking. The water leaves the resistor

Risto

CH

as a mixture of water and steam, passes into the condensers, and is returned to the con-

A 3000-gallon tank for the two-cent-per gallon fuel oil is installed near the rear of each of the cabs, next to the condensers.

An ingenious control system maintains steam flow in proportion to the load on the turbine, as well as a constant steam pressure When the engineer moves the throttle shead, the control functions to increase the amount of fuel, water, and combustion air to the boiler, and the demand for more power from the generating plant is satisfied The process is simply reversed when the enof the fuel, combustion air, and water supplied is a fixed relationship, regardless of the main power demand.

An auxiliary turbine set drives a combustion air blower, feed water pump, and fuel oil pump through gear reduction units Getting the locomotive "steamed up" prepara tory to running is a simple matter compared with the process of getting the standard steam locomotive ready for service. A small vertical fire tube boiler with a capacity of 100 pounds of steam per hour is used Propane gas serves as the fuel in this boiler If steam can be secured at a roundhouse or from some other external source, the main hotler can be started without the use of this auxiliary boiler.

The running gear of each unit of the steam-electric locomotive consists of two main driving truck frames, each carrying three driving axles The two-axle guiding trucks proted to the main truck frames complete the running gear of a 2 C-C 2 wheel arrangement

Crew space is up front, instead of at the rear of the unit as in the reciprocating steam locomotive, and from his comfortable chair the engineer can look out over the soulnose of the steam electric locomotive and get a clear and unobstructed view of the track ahead A defrosting system and will ers keep the windshield clean in sleet, snow, and rain storms. The engineer operates the locomotive by manipulating two controller handles and the usual air brake system, and as a final modern touch he even has a handset telephone handy at his elbow so that he can be in instant touch with other members of the crew

What effect this new steam-electric locomotive will have on the future of American railroading, only time can decide. Among already-known advantages, the steam-electric locomotive has a thermal efficiency from fuel to the driving wheels more than double that of the conventional locomotive. Its ability to travel as far as 700 miles under favorable conditions without stops for fuel or water, plus inherent high rates of acceleration and braking due to high adhesive weight, are important factors in maintaining high speed schedules on long runs. There will be say ings in brake shoes and wheels for the entire train as well as for the locomotive as a result of the electric braking. Boiler trouble should be rare, due to the use of distilled water in a closed system which eliminates corrosion and boiler scale.

It is certain that the performance of the new steam-electric locomotive over the historic line between Chicago and the west coast will be watched closely, for it represents the latest manifestation of that "breeding" of unlimited possibilities to which Horatio Allen referred 110 years ago.

CAMERA ADVENTURES IN WASHINGTON

THIS month we relinquish the chair to a guest conductor, no less than Mrs Cancera Angles, herself an enthusustic fan, who describes the opportunities for picturemaking which she found on a recent vivil to the Nation's Capital

In the most national capitals. Washington very dome ratio, photograph radii into the very dome ratio, photograph limited anyway, and the Senate and House alleries, where they would be unlimited, not only are you permitted to earry your camera mit public buildings but the guards encourage you by pointing out interesting pritting road-blicker. This camera fan took prittures mostly of extense of buildings in no full bloom. However, many striking wress can be taken from the windows of the Capital Capi

"Washington Sunset"

public buildings From the top of the Washington Monument which towers over the city, you can—if you can elbow your way successfully to the windows before other camera enthusiasts monopolize the best vantage points—get interesting bird's-eye-view shots of Washington.

Of all the buildings, the Lincoln Memorial lends itself best to picture taking because of its dominating position on the banks of the Potomac, and the wide spaces around it which permit the photographer to view it from every possible angle. Its majestic pillars cast striking shadows against the dazling white walls. From the top stairs, front, one gets a sweeping view of the Potomac; from the back, an interesting view of the reflecting pool extending from the Washington Monumeat to the Lincoln Memorial which, on a clear, windless day, mir rors both structures.

Other interesting picture possibilities are to be found in the Botanical Gardens, with its lewildering array of plants, flowers, trees, and so on, from all parts of the world, in tropical or other natural settings. You can

"Public Model"

stroll unmolested through the White House grounds (inside it is necessary to check cameras) but visitors are permitted to view only a few rooms. The White House lends itself to interesting shots both by day and by night, when it is bellikuluk illuminated.

when it is brilliantly illuminated.

If, however, you don't take to buildings,
exteriors or interiors, you can always wander down to the Tudal Basin—If you happen
to be in town during the cherry blossom
estival. The shot reproduced here was taken
on such a stroll when the sun was playing
lude and seek and the picture had to be
focussed in advance and snapped the
moment the sun came out of bhiding. You can
walk clear around the basin along a path
which hugs the weter's edge. If the view
which hugs the weter's edge. If the view
sufficiently, you can do not intrigue you
sufficiently, you can can be also always of the you

The Tidal Basin always attracts a good crowd and something interesting is bound to happen. The picture of "Daniel Boone," was taken the first day your photographer arrived in Washington, "Daniel Boone," spotting our camera, greated us with a beatry mult and an even hearite offer to hearty mult and an even hearite offer to corned his offer until a more charitable photographer of the male sex took him up not it. To express his appreciation, Daniel showed the young man, and an ever increasing throng which crowded around hum, pictures which had been taken of Daniel in a Rossaan costume by a dentat photographer in the U. S. Navy, He also showed us pictures in which he anoneard with Herby

"At the Concert"

Lamarr in connection with one of her recent

Relenting, we accepted his offer but had considerable difficulty in getting him away from the crowds as well as inducing him to avoid posing. As his photographic income soared, he became even more loquacious. He is apparently a well known character and takes parts in historical pageants, fairs, and so on. Two young ladies from Philadelphia identified him as having ridden in a historic carriage during a celebration there. To us, Daniel confided boastingly that he expected to be at the World's Fair with Ford or some other exhibit, All the while, he never for a moment lost sight of prospective photographic victims. If an uncharitable photographer tried to shoot without paying. Daniel would pursue him, with the crowd after him, crying out that this was money he needed for food and lodging. When we finally parted, we gave him the address of Mr. Camera Angles in the event that he does turn up for the World's Fair.

Just before leaving the scene of this adventure, we could not resist taking a shot at the sunset on the waters which, though ordinarily like a mirror, had been made turbulent by a strong wind. Fortunately, we had remembered to bring a lens shade, tor without it, this picture would not have been attempted.

On our last day in Washington, Marian Anderson was singing before a record crowd at the Lincoln Memorial. Because one of the guards had said he would be "shot" if we tried to allp under the ropes which held back the throngs, we had to content ourselves which held back the throngs, we had to content ourselves which held back the throngs were not the transfer soint.

that vantage point.

The camera made many new friends for
us. We found this time, as we had on so many
previous occasions, that not the least of the

values of sightseeing with a camera are the exerting adventures to which picture taking invariably leads

CAMERAS AT THE WORLD'S

WE have it on the word of the officials of the New York, World's Fair that pho tography by amateurs will be freely permited and, in fact, encouraged The only restrictions on this wore are that professional will be barred made the professional concession at the Fair has been awarded to Underwood & Underwood, Incidentally, the Eastman Kodak Company will do its own large that by sponsoring photographic exhibitions by sarrous organizations and by helping amateurs in their exposure and other photographic problems at the Fair. One of these helps will consist of specially built backgrounds against which the amateur may photograph his best girl, and were versa.

PRESS CARDS

This notion seems to have gone abroad that a press card is something that may be purchased and automatically will admit be holder to all functions. The only press card of any value is one issued by the Police Department of the particular cyt in which pictures are to be made, and money will not hop it. It is suiced only to accredict working press photographere associated with specific mewapapers. In New York City, the press cards are dustributed by a central news but cards are entired to the cards are entired by the Police Department, and are issued for three months as a time.

PRINT THROUGH THE

BACK

I prour negative looks too sharp for the piecure's good, you may find the solution in projecting your negative through the back of the printing paper rather than by the normal procedure of directly onto the emulsion. The negative is reversed in the holder—that is, with the emulsion side facing the lamp rather than the lens—and the paper is turned upptied down. If your casel has any metal or the paper is turned upptied down. If your casel has any metal or

other bright parts built into it, cover the casel with an ordinary sheet of paper and then place the printing paper, face down, on top of it Either single weight or double weight paper may be used, the double weight naturally requiring a longer exposure than that needed for the single weight

NEW PHOTOGRAPHIC TERM

THE ever-widening use of exposure meters of all types has recently brought into vogue a brand new photographic term de scribing the act of using a meter to "read exposure. The term is "expometering," and is introduced by Joseph M. Bing, FRPS It seems that photography is destined to make its influence felt in the dictionary as well as the many fields it already touches

"DESIGN IN SUGAR CUBES"

TWO separate exposures of a simple setin mind than to give one a little more time than the other, provided the inspiration for the combination of the two negatives reproduced here Accidentally, one day, the two

Start of an ineniration

negatives being enclosed in the same glassine pocket, we looked at the negatives against a light and saw what we thought was an unfamiliar negative Actually, the two negatives were so positioned that they provided a strange nattern very much resembling a caricature of a human figure. So the two were placed in the enlarger as they were, with the emulsion side of one facing the easel and the emulsion side of the other facing the light A rather long exposure was required,

for one reason because two negative densities were being exposed, for another because of the overall density of the individual negatives Had the job been done according to a pre conceived plan, a darker background would have been employed in order to provide greater transparency, although in that case the shadow effects would have been less pronounced.

"KITTEN ON THE WINDOW SILL"

EVERY morning, some time before eleven, this white kitten sits on the window sill of the apartment just below ours, bathes itself in the sun and surveys the world below it. Our appearance at the window above at tracts her attention and she watches us through one of the window panes, particu larly attentively if we happen to have a camera in hand. One such morning, it occurred to us to expose a negative to this matutinal habit and the picture you see is the result

"Kitten on the Window Sill"

In making the enlargement we lined up the edge of the wall with the long side of the print in order to overcome the tilt in the camera position necessitated by the subject The angle is, however, identified by the diagonal lines of the upper and lower parts of the window as well as the diagonal lines of

"CORRIDOR CEILING LIGHT"

THE opportunities for pictures that he even in humdrum subjects is illustrated by this shot of the interesting pattern surrounding a small ceiling light. Waiting for the elevator sometimes has its advantages, for it was on one such occasion that we happened to be studying the ceiling-for lack of something better to do-and, noticing the practically symmetrical arrangement of the pattern "leaves" all around the lamp, thought of the camera hanging idly from the shoulder. It required a low, crouching position and a straining of the neck, the camera being of the range-finder type, to get into as central a position as possible under the circumstances, short of lying on the floor. At the full f/2 opening of the lens and with fast pan-

Dozens of Illustrations chromatic film, we made three shots, at 1/10, 1/25, and 1/50 of a second. Although we knew we could not fail to record the light, our chef concern was with the shadows which were projected upon a relatively dark ceiling. Also, because we were shooting directly into a light source, we expected flare

"Corridor Ceiling Light"

and were not sure just where this would street the film In one of them, luckly, the flare struck just outside the ring of shadows and we were able to make a print by excluding this flare spot through appropriate cropping. The square composition was inevitable because of the nature of the subject.

PHOTOGRAPHIC EUROPEAN TOUR

Tame picture train idea, started some time assume the ambitious proportion of a Frist Annual Photographers' Grand Tour of Early, or Ridgewood, New Jersey, this first Encopen photographic tour, by private motor coach, as to have as as photographic leading and mentor, the well-known pictorialist, Edward A. Alemus, F.R.P.S., who will be the lecturer, advisor, and consultant on all phases

of photography.

The tour will begin on August 11 and will last through September 25, during which period the following countries will be visited: England, Holland, Belgium, Switzerland, Germany, Italy, and France.

ANNUAL LEICA EXHIBITION

This annual assembly of the best Leica photographs made during the course of the year is now under way. Leica users are advised that no specific restructions are placed on the choice of subject matter, which may be aptrain; an aeral, candid, action, medical, animal, insect, or any other type of picture. Actual color prints made from Leica color transparencies are also invited, as well as sequence pictured.

The rules announced for submitting prints to this, the Frith Annual Leica Exhibition, are as follows: There is no limit placed on the number of prints that may be submitted; prints should not be less than 8 by 10 inches in size; prints may be submitted mounted or unaquanted, but if mounted do the measure of the prints should be of a light color and conform to the standard size; on the back of each print or

mount, the photographer should include his name and address; the lens used; shutter speed and diaphragm opening; film used, developer for the film; filter, if any, as well as other accessories used to make the picas other accessories used to make the pic-ture; and, if possible, the name of the paper and the developer used to make the prints. Contact prints should accompany photo-graphs but should not be pasted on the mounts; all packages should be addressed to E. Leitz, Inc., 730 Fifth Arenu, New York, N. Y., and should hear the word EXHIBIT in the lower left corner.

SHOOTING IN THE BACK

OCCASIONALLY you run across a subject, such as a broomstick vendor, with brooms of various descriptions jutting out from under his arms and over his shoulders, which presents an opportunity for a shot in the back. These persons are usually on the go so it will be necessary to follow the subject and shoot as best you may. A good way to keep him in focus is to set your camera for a given distance, walk briskly or slowly, as the case may be, until you reach this distance between camera and subject and let the latter's walking speed pace your steps. When the moment seems ripe, shoot quickly and use a relatively fast shutter speed as a precaution against camera unsteadiness at the moment of exposure.

WHAT'S NEW

In Photographic Equipment

Alf you are interested in any of the items described below, and cannot find them in a detertising columns or at your photo graphic dealer, we shall be glad to tell you where you can get them. Please accompany your request by a stamped envelope

ROBOT MODEL II: Newly designed model with features including optional fitting of Zeiss Biotar f/2 lens and Zeiss Telephoto Sonnar f/4, 7:5cm. In addition to Model I features, Model II offers new film magazine for Robot daylight spools, as well as all films wound on standard 35mm cores; bulk film may be used with or without spool; built-in flash bulb synchronizer coupling, for use with new Robot Sequence Flasher, per-mitting sequence photography at night. Flashgun changes electrical contact from one bulb to next automatically, and operates as fast as shutter release can be worked, camera shutter being its own synchronizer.

PIERCE EXPOSURE METER (\$1.85): Optical type meter. Entirely pre-settable, no calculations required. Film speed and filter factor, once having been set, need not be changed until filter or film is changed. Each meter complete with neck cord and packed in individual box complete with instructions for operation and listing in Weston system of 79 different emulsions. Two models available, for motion picture and still cameras.

MODEL C OMEGA ENLARGER (\$97.50): For all negatives from 35mm to 3¼ by 3¼ luches. Enlarger design similar to that of Model D, with side negative troughs. Enlargement ratio 8¼ times with 3½ inch lens,

DUROPOD (\$3 to \$6): Tripods characterized by light-weight, sturdiness, and long leg extension. Special reversible feature of legs permits head to be used for either American or German tripod bushings. Six different models available, ranging from three to eight sections. Finished in brass and stainless steel.

CAMERATROL (\$19.95). New synchronizer for Photoflood bulbs, with remote control unit for photography by Photoflood light With unit in place bulbs burn at ordinary brilliance of household lamps during preliminary focusing, composition, and placing. With shutter of camera set on bulb, operator presses remote control switch, which opens shutter and brings hulbs to full brilliance at same instant. Releasing remote control switch closes shutter and reduces power feeding bulbs at same time.

UNIVER MERCURY 35MM CAMERA (\$25): Equipped with / 3.5 lens and focal plane shutter with speeds from 1/20 to 1/1000 of a second Also equipped with f/2 lens. All adjustments on front of camera. Equipped with built-in Photoflash synchronizer and automatic film transport synchronized with shutter winding knob Exposure calculator and depth of field scale he close to built-in parallax correcting view finder. Camera measures 5746 by 2½ by 1% inches, weighing 18 ounces. Seventeen focusing mount graduations allow approach as close to subject as one foot, six inches. Camera body of polished aluminum and genuine leather snap-closing casing. Film available in three types: Ultra Chrome for normally lighted action: Microtomic, fine grain panchromatic film; and Ultrapan, ultra-fast panchromatic film for use under adverse photographic conditions. Complete line of filters available made of fine ground optical glass, mounted in dead black brass mounts. also improved type of polarized filter.

KODASLIDE READY-MOUNT CHANGER (\$12): Magazine-feed device for Kodaslide Pro-jector Model 2 intended for use in showing

groups of Kodachrome still transparencies or black-and-white film positives in new Ready-Mounts, Combination particularly useful for schools and illustrated lectures be-

fore small groups, as well as for home prosection Once supply magazine of Ready-Mount Changer is charged with group of slides, operator can show complete sequence without removing eyes from screen. Up to 50 Ready-Mount slides may be placed in supply magazine at one time. Slide-shifting mechanism operated by flexible 30-inch plunger resembling cable release but larger. Pressing in plunger moves slide into position; pulling it out readies it for fol-lowing slide. Changer made of aluminum with small parts in bright metal.

JACOB DESCHIN, conductor of our "Camera Angles" department, will answer in these columns questions of general networts of manufacture photographers. If an answer is desired to mail, enclove a stamped, addressed newloop. Queres should be specify, but MT Develon cannot undertake to draw comparisons between manufactured products nor to advise on the purchase of equipment or materials.—The Eddier

Q. Occasionally, in exhibition prints, I notice a fine lustre which appears to be a surface treatment. Can you tell me how this is done? —C. L.

A. Mix equal parts of olive oil and turpentine and apply evenly over the surface with a wad of cotton, following this by polishing with a soft cloth. Another popular formula includes

Benzol 8 ounces
Becswax 1 ounce
Rosin 14 ounce
Turnentine 2 ounces

Pour a little of the solution on the print and then rub in with cotton. When the entire print has been treated in this way, polish dry with a soft cloth or a fresh pad of dry

Q. Not being too familiar with the various makes of photographic lenes, 1 on at a loss in making a selection. I am on the properties of a twin-lens 2½ by 2½ reflex type cameral which would be the more desirable, one equipped with a Rodenstock Trians to 1/300th, or one having a Heliar 1/3.5 lens in a Compur Rapid shutter, 1 second to 1/300th—T. Cs. 2 second to 1/300th—T.

A. For all practical purposes, one lens will give a good a performance as the other Your choice, therefore, must be on the abase of the other factors involved, the higher lens speed of the f/20 over the f/35, which is negligible, and the difference is the top shuter speeds. It would seem that the choice would depend cheely on the design of the camera. Basically, they are the same, of course, but there are other factors which, in a personal estimate, would place one camera above the other.

Q. Can you cite me references to information on the hypersensitization of film by mercury vapor? Also on the subject of photography by infra-red light?

—J. A. M.

A. The method of dry hypersensitizing with mercury vapor is fully described by the discoverers, Dr. F. Dersch and Dr. H. Luerr. of the Agfa Ansoc Research Laboratories, in the report of their experiments printed in the Journal of the Society of Motion Printing Engineers (Vol. XXVIII, No. 2).

We believe that you may be able to obtain a reprint of this report by writing to the Agfa Anseo Canapay at Binghamton, New York, On the subject of infarered plotted they always in the Extinan Kodak, Company publication, "The Photography of Codord Objects", no N. G. Rawlings, "Infar Red Photography", and to Dr Othmar Helsichs has "Practical Infar Red Photography".

Q. At what aperture does my //2.8 lens reach its maximum resolving power?—D. G. L.

A Generally, this occurs at the stop [7:56], that is, two stops smaller than the maximum aperture of your lens. For this reason, if perfect sharpers is what you want, you would do heat to try to work at this aperture whenever possible Of courses, stopping down will give you greater depth of field, in which case you will be willing to service power as [7:56] or the sake of including more planes within the field of relatively sharp foreis.

Q. Is there any means of achieving an //64 aperture on my three-inch lens by means of a sort of Waterhouse stop? —A. L. W.

A. The stop / 22 as the smallest that has been found practical with leaves of this short focal length, but the great depth of their minimum control of the short focal length, but the great of the short focal length are the short for the short focal length of the short focal len

Q. My camera case has been used so long that it could stand a little reconditioning. What is a good polisher for this purpose?—D. K.

A. Propert's Saddle Soap is a standby with many. An excellent formula that you can make up yourself and rub into the leather with a soft rag consists of 50 parts lanolin, 40 parts castor oil, and 5 parts each of sodium stegrate and japan wax.

Here is the latest streamlined addition to the popular lace of holling 50 mm imilatures it is remarkably light and compact, yet be a precision instrument in curve were of the world Among the many features is a built-in range finder—knowsyn thromized and optically perfect—operating on the spitt-image principle All control parts are cash to have and updated for the properties of the spitt succession. It is provided for taking pictures in rangel succession in the process of the spitter of the spitte

BURLEIGH BROOKS

TELESCOPTICS

/=

A Monthly Department for the Amateur Telescope Maker Conducted by ALBERT G. INGALLS

TO Nature (London), in which scientists regularly report progress in their work for the information of other professional scientists, Dr. Welter S. Adams, Director of the Mt. Wilson Observatory, has given the account of work preliminary to final figuring of the 200° mirror which follows.

The present figure of the 200" mirror approximates closely that of a sphere with a radius of curvature of 111 feet. The disk was first shaped on front, back, and edges by grinding with coarse Carborundum and the center was then hollowed out to a depth of about 3%" with the aid, first of a 50" tool, and then of successively larger tools up to the full size of 200". As the spherical figure was approached, finer grades of Carborundum were used, so that when optical tests became necessary only a few hours of polish ing were needed to give the surface sufficient reflecting power. During the first stages of work upon the disk, the cylindrical holes on the back of the mirror and the large areas between the supporting ribs were filled with plaster of Paris, and after the face and back had been made parallel the 40" opening at the center of the disk was closed with a glass plug weighing about one ton. The plaster of Paris was removed when the surface had reached nearly the required form, and the mirror was placed upon rubber pads which rest on the frame of the support system of multiple counterweighted levers. The friction of these pads was required to neutralize the strong lateral pull of the grinding and polishing tools making contact over so large a surface, and for this reason the horizontal plates of the supporting system were not engaged. The optical tests, however, were made with the mirror vertical and balanced upon the support system just as it will be wh in use on the telescope. Future optical work, including the parabolizing, will be carried on with the mirror resting upon the rubber pads; but these will be removed when the figuring is completed

"From the first the optical tests of the mirror proved to be most satisfactory No

change was seen in the figure when the mirror was tipped repeatedly from a horizontal to a vertical position or when it was rotated. Also no local deformations could be detected at the points of contact of the 36 individual lever supports. In fact, the support system was found to be performing quite as well as had been hoped by its designers. The length of the radius of curvature proved to be about 2" less than had originally been planned, but this slight difference, amounting to about I" in the focal length is far within the limits allowed for in the design of the telescope, and it is probable that no attempt will be made to reduce the amount through polishing. The surface was found to be reasonably free from zones. but a small amount of astigmatism was pre ent amounting to about 0.1" in the optical cut-off at the center of curvature. This proved to be due to a slight deformation of the disk caused by the horizontal pads upon which the mirror rests. [Supplementary note added in letter from Dr. Adams to Scientific American, to bring article up to a later date:
"Through suitable changes in the supporting pads this astigmatism has now (March 15) been eliminated by a small amount of fine grinding and polishing. The zones have also been considerably reduced and the entire mirror surface is nearing an accurate spherical figure. Work will soon be commenced upon the final figuring of the 120" plane mirror to be used in testing the parabolization of the 200" surface."

"Although the final parabolic curve of the surface of the mirror will be only 0005" deeper than the spherical curve, the area is so great and the process of polishing so slow that it is planned to make most of the change through fine grinding and to leave but the final stages of the figuring to the polishing tool. The procedure has already been found auccessful in figuring the spheri

"Accurate tests of the parabolic figure of the 200" mirror will require the use, as an auxiliary plane, of the 120" mirror. The completion of this mirror will be one of the next major undertakings in the optical shop. It is at present shaped on front, back, and edges, and the surface has been ground approximately flat. It is planned to figure the three auxiliary hyperbolic mirrors, one for the Cassegramian and two for the coudé combination, by the method devised by Hindle, without the use of the 200" mirror. Four spherical mirrors, each about 40" in diameter and with a radius of curvature of 25', are being prepared for this purpose, two being very nearly completed. The mirrors will be used side by side in a cloverleaf pattern and provided with adjustments for bringing their centers of curvature into accurate coincidence

"A few figures are of interest as indicating the scale of the optical work on the 200° mirror. About five tons of glass have been removed in the process of shaping and figuring, and about 20 tons of Carborondum have been used for grading. During the polishing, about 30 pounds of rouge an hour is the average consumption with the full isselt tool, and but a small fraction of this material can be salvaged. As a result, rouge has been purchased in quantities hitherto quite timilate to dealers in optical supplies."

IF you can train your eyes to perform south abby, you can train your eyes to perform south abby, you can be an outperform the two images shown in Figure 1 and obtain a three-dimensional view of the 200° mirror and of the lettered image. You are standing in the loty to the contract year of the performance of the contract of the contr

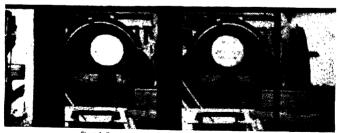

Figure 1: Stereoscopic views of the 200" telescope and reflected image

approximate eye level and 2' or so in front of the window. In Russell Porter's words. 'you'd swear the image was material. Startling!" It seems to hang in space and you feel the urge to feel of it, others comment.

Thus far, however, there is nothing stereoscopic about it; in fact, the stereoscopic part has no connection with the apparatus or mirror but was obtained by taking two photographs from the visitor's gallery, the second one made with the camera shifted sidewise about the same distance as the separation of the average man's eyes. These photographs were taken by David O. Woodbury, an amateur telescope maker who, after spend ing several months in Pasadena and Mt omar, has written a book about the 200" telescope, one chapter of which was recently pre-published as an article in Reader's Digest (the entire book is due to appear in October)

There are three ways to get the threedimensional effect (1) use a mounted pair of prismatic lenses; (2) hold a long strip of cardboard between the end of your nose and the center of the pair of pictures, so that the right eye sees the right-hand picture alone and the left eye the left-hand picture alone, and then try to drift off into a focus on infinity (think dreamily about that brunette), or (3) command your eyes to do the trick without any cardboard-this can be done by many, after a bit of practice

The square object in the immediate foreground is a rack to carry the knife-edge, when the mirror is tested à la Foucault

RECENTLY, in one of the innumerable ror as a "lens," your scribe was further enlightened by the statement that a "lens" had been "polished with face powder!" It isn't difficult to figure out how this howler happened, but then followed this thought. "Could a passable polish be had with face rouge, and just what is in face rouge, any way?" Will some face rouge away?" way?" Will some face-rouge-experienced

ANNOUNCEMENTS: Stellafane conven-tion will be held on Saturday, July 22-R. J. Lyon, Secretary, Springfield Telescope Makers, 252 Summer St., Springfield, Ver-

MARI CROSSWENDT 31 W 87th St. New York, Secretary of the Optical Division of the Amateur Astronomers Association, New York City, states that the Optical Division (which is simply the for mer New York Telescope Makers) cordially invites all amateurs who visit the New York World's Fair to inspect its workshop deep in the bowels of the earth under the Hayden Planetarium, at 81st St. and Central Park West. It asks that, if convenient, such visitors first notify the Optical Division by relephoning as follows: Mon., Tues., Wed., Thurs., Fri., 10 to 4, ENdicott 2-8500, Ext. 478; 6 to 9, Ext. 509. Sat and Sun., 2 to 9, Ext 509. Even if you lack opportunity to make such arrangement, the planetarium guard may by luck find someone in the optical workshop. Planetarium performances, which you may wish to combine with this visit, take place weekdays at 2:00, 3:30, 8:30. Saturdays at 11:00, 1.00, 2:00, 3:00, 4:00, 5:00, 8:30. Sundays and holidays at 2.00, 3:00, 4:00, 5:00, 8:30. An exhibition of products of amateur as ners' activities will be held in an adjacent building from July 30 to Aug. 20,

THE REGISSER'S CORNER

PROSPECTIVE beginners at telescope making very frequently have attacks of deep-dved doubt regarding their ability to make a telescope, and to these we commend the two photographs reproduced here, showing telescopes made respectively by an 11year-old lad and a lady. Not that telescope making is a juvenile or feminine hobbyin most cases it pretty definitely isn't. Simply. these telescope makers are beyond average in ability, for age and sex, but not men-

Donald Bird is the youth and Wallace (

Donald Bird and his telescope

Swank, science teacher at the Eaton Rapids Public Schools, Eaton Rapids, Mich, sends us an account of his success, stating that Donald was 11 years old when he finished this telescope Some of your readers may think," he continues, "that Donald did perhaps a little of the work and an older person most of it but such is not the case, he dul et all His mirror is 414" in diameter with focal length 34", and is mounted in an octa-gonal tube of plywood. He used pipe fittings for the mounting" to far as the conductor of this department can recall, Donald Bird is the youngest lad to have made so creditable a telescope. Natural mechanic.

The lady in the other photograph is Mrs Albert M Bonelli, 2515 Drummond St., Vicksburg, Miss, and she states that "the

Mrs. Ronelly and her reflector

in Scientific American that it wasn't impos sible for me to do what others had done, and that I might realize a life's ambition by making and owning a telescope So I obtained a kit of materials, your instruction book 'Amateur Telescope Making,' and got busy This 6" reflector was the outcome, after 72 total hours of hard work

In difficulty the amateur telescoptical hobby starts at the level of work such as these examples and may be made to extend just as far as the follower cares to extend it toward and into really advanced work

ROM a very old hand at the telescope making hobby, Harold A. Lower, of San Diego, we receive the following comment: "Here is something I think you ought to bear down on, in your Beginner's Corner-the chapter in 'Amateur Telescope Making' on zonal testing. I have found that there are a surprising number of amateurs, some of whom have made several mirrors, who don't even know that chapter is in the book. Lots of them think all they need to do is use a Ronchi grating, and polish until they get curved lines. Naturally, the result is usually a deep hyperbola. Honestly, I think there would be more good mirrors if the Ronchi test had never been heard of. It is useful, of course, but most beginners depend on it too much

The chapter on zonal testing extends from

inclusive, and a convention of amateur as Intronomers will be held on August 19 and 20 In "Amateur Telescope Making Advanced," the sequel book to "Amateur Telescope Making," H. E. Dall describes the camera obscura, which is essentially a refracting telescope for use from indoors. The first since then to make one is William R. Crosby, 566 Glide St., Rochester, N. Y., a trosby, 500 time 7tt, nonnester, it. 1., a member of the thriving group of amateurs in that city Figures 2, 3 and 4 show the design and construction. At the top, in Figure 2, is an elevation showing a roof and, pro-jecting above it, a flat both pivoted and rotatable. This picks up rays from any chosen object and directs them downward through the objective lens shown, which projects an image on a horizontal viewing table several feet beneath. Here the image may be viewed with the eye or, if still higher magnification is desired, with a microscope called a viewing telescope. The lower elevation shows the apparatus from another quarter.

Crosby, however, did not build his camera obscura into his house but into his automobile trailer. Figure 2, taken outside, shows the trailer roof and the raised flat, while Fig-

INVENTION QUESTIONS ANSWERED!

SAVE TIME and MONEY Know the Rules Governing PATENTABLE Invention

INVENTORS, ENGINEERS, EXECUTIVES, LAWYERS FIND THIS A BOOK OF DAILY PRACTICAL VALUE

VITALLY INTERESTING and authortative for all who deal with inventionathis readable book and ready reference manual gives you the essential principles of Patentable Invention—from 700 actual cases in the Courts! The established RULES used in determining the question of Invention—are clearly, concisely, accurately stated. Two outstanding sections in particular—What is Invention and What is not Invention make the work invaluable.

317 pages are packed with specific information on actual cases. Illuminating chapters on the Background of Invention, General Characteristics of Invention, the British Rule Thus splendd presentation of the legal side of invention is highly recommended to the Jayman It can help you to cooperate with your attorney to greater advantage.

Patent, Trade Mark, and Related Legal Proceedings That May Have a Direct Effect on Your Business

By ORSON D. MUNN, Litt.B., LL.B., Sc.D.

New York Bar Editor, Scientific American

FAIR NEWS

THE New York World's Fair Corporation has recently restrained a publisher from using the title "Illustrated Fair News' in connection with a magazine relating to the New York World's Fair. The publisher originally published a magazine entitled "World's Fair News" and the New York World's Fair Corporation obtained an in junction restraining him from publishing a magazine under that name. Shortly after the original injunction was issued, the defendant indicated his intention of using the name "Illustrated Fair News" in connection with the magazine and the New York World's Fair Corporation made an application to have its injunction extended so as to restrain the new name. The Court extended the injunction and restrained the use of the new name on the grounds that the publication "was obviously designed for the purpose of enabling them to continue their exploitation for business purposes of the possibilities arising out of the World's Fair

EXPERIMENTATION

A PATENT for a process must fully decarried out by the proverbial "man skilled in the art" without the necessity of any further experimentation. If further experimentation is necessary to carry out the process, the patient is invalid for the reason that it is indefinite and does not fully disclose the

This principle is exemplified by a recent suit for patent infringement which involved a patent for a process for propagating yeast in which the production of alcohol is reduced to a minimum. In describing the process the patent suggests that seed yeast be placed in a wort having a specific gravity of one degree Balling After the process of reproduction is initiated, concentrated wort having a specific gravity of approximately 12 degrees Balling is slowly and substantially continuously added to the original wort over a pro tracted period of time. The patent states that the concentrated wort should be added "at a rate such that not only the alcohol which may have been formed from the quantity of sugar present in the diluted portion of the wort, but also any alcohol which may be formed from the sugar which is present in the added wort, can be assimilated immediately by the yeast."

The Court held that further experimentation was necessary in order to ascertain the times and manner in which the concentrated wort should be added. For this reason the Court held that the pattent was indefinite, did not fully disclose the invention, and accordingly was invalid. In reaching this conclusion the Court made the following statement.

"But even if the process disclosed by Haydnek be held to constitute invention, the patent is invalid for indefiniteness as was held by the learned District Judge Both the times and manner in which the concentrated mitten solution is to be added may be assertianted, as we have stated, solely by experimentation. The disclosure of the patent is therefore too wague and indefinite to constitute invention."

DOUBT

IT is an established principle of pattern law bit in a state of the presentation of patent applications all doubts with the prosecution of patent applications all doubts with the regard to the question of invention must be been expected in favor of the applicant. Thus in a case where doubt existed as to whether the advance made by the applicant for a case where doubt existed as to whether the advance made by the applicant for a patent rose to the dignity of invention or merely amounted to mechanical skill, their cooled in favor of the applicant and accordingly a patent should be carried in the property of the applicant and accordingly a patent should be

In a recent case involving an application for a patent on a method of making artificial sausage casings the Examiner had originally held that two of the claims were patentable Thereafter the Examiner reversed his de cision and held that the claims in question were not patentable. On appeal to the Court of Customs and Patent Appeals it was con tended by the applicant that the Examiner's action in originally allowing the claims, and then rejecting them, indicated that there was some doubt on the question of invention It was argued that in accordance with th principle set forth above the doubt should be resolved in favor of the applicant and the claims should be allowed. The Court of Customs and Patent Appeals rejected this contention and held that the mere fact that the Examiner had reversed himself did not indicate that there was doubt on the ques tun of invention

BREATHING

THE word "breathing" as applied to textile fabrics was held to be descriptive by the Court of Customs and Patent Appeals and accordingly not registerable under the Federal Trade Mark Act of 1905.

A textile manufacturer attempted to resister the words "Breathing Back" as a trade mark for pile fabries having an adhesive coating on the back thereof which was impervious to water but pervious to gases and air. The registration of the manufacturer on the grounds that the words "Breathing on the grounds that the words "Breathing".

Back" were merely descriptive of the characteristics of the pile fabric. The Court found that the word "breathing" had been used for many years to describe artificial leather and certain fabrics which were persons to gases and air. It was accordingly concluded by the Court that the words "Breathing Back" were merely descriptive of the persons characteristic of the pile fabric and under the crecumstances the words to the contract of the contraction of the pile fabric and under the crecumstances the words to rendering its opinion the Court stated as follows:

"We are of the opinion that Breathing Back' as applied to applicant's goods does nothing more than to describe the character of the back of applicant's pile fabric which, by reason of its porosity, permits breathing or passage of the air through the back."

ANTENNA

In a recent case of importance to the radio communications industry the United States Supreme Court held that a patent on a directional antenna was not infringed by antennas employed by one of the large ladio communications companies.

The Court found that the patent in suit related to a V-shaped wire antenna based on the so-called "Abraham formula," which provides that when radio activity is projected from a charged wire having a length which is a multiple of one half the length of the waves projected by the antenna, the angle of the principal radio activity is a function of two variables, namely, the wavelength and the number of half wavelengths contained in the wire. The patent in suit set forth an empirical formula based on the "Abraham formula" for determining the most efficient angle for disposing the wires in a V-shaped directional radio antenna. The Court found that the patent, being based on the "Abraham formula," strictly limited to an antenna in which the length of the wire was a multiple of onehalf wavelengths. All of the antennas emplayed by the defendant, with the exception of one, were found to have a length which was a multiple of one-quarter wavelengths but not of one-half wavelengths. These antennas were held not to come within the "Abraham formula" and not to infringe the patent.

The remaining antenna which had a length which was a multiple of one-half wave-lengths was found to be disposed at an angle smaller than that prescribed by the formula set forth in the patent in suit and it was held not to be an infringement

SPACHETTI

MANY enginest exters will no doubt be annoyed by allegations of the Federal Trade Commission that the authenticity of sughetitis is not determined by the length thereof. In a recent proceedings mentioned by the Federal Trade Commission against a manufacturer of spaghett and mearons it was charged that the manufacturer was guilty of unfair methods of competition because his advertising matter stated that mearons and spaghetts not made in long lengths was not greater. The Commission ceptive, and misleading and the manufacturer was ordered to show cause why he should nut cease and desist from making further representations of this dapageter.

Are You-

putting your spare time to good advantage?

one of the many who are seeking a new field to en-ter?

"seeking a means to save money wherever possible?

If you are, here is a practical solution to your problem.

HOPKINS' CYCLOPEDIA OF FORMULAS

Is the foundation for the beginning of a fascinating hobby; the groundwork on

which to build a practical knowledge of useful chemical facts.

Is the foundation for hundreds of suggestions for those who are seeking salable articles which can be manufactured at home profitably on a small scale.

IF you want to save money on wines and liquors: your dyes, inks, polishes, soaps, paints and varnishes, adhesives, antiseptics. bleaches, cosmetics, etc.

You can profitably make them from the 15000 formulas contained in the 1077 pages of

HOPKINS'

Cyclopedia of Formulas \$5.50 postpaid (domestic) For sale by

For MEN

who want to become independent in the NEXT TEN YEARS

IN the Spring of 1949 two business men will be sitting in a mid-town restaurant. "I wonder what's going to happen next year," one of them will say, "My business is fine now-but the next few years are going to be hard ones, and we may as well face the facts."

The man across the table will laugh.

"That's just what they said back in 1939," he will answer. "Remember? People were looking ahead apprehensively-and see what happened! Since then there has been the greatest growth in our history-more business done, more fortunes made, than ever before. They've certainly been good years for me."

He will lean back in his chair with the easy confidence and poise that are the hallmark of real prosperity.

The older man will sit quiet a moment and then in a tone of infinite pathos:

"I wish I had those ten years back," he will say.

· Today the interview quoted above is pittely imaginary. But be assured of this-it will come true. Right now, at this very hour, the business men of America are dividing themselves into two groups, represented by the two individuals whose words are quoted. A few years from now there will be ten thousand such luncheons and one of the men will say

"I've got what I wanted."

And the other will answer.

"I wish I had those years back." In which class are you putting yourself? The real difference between the two classes is this-one class of men hope vaguely to be independent sometime, the other class have convinced themselves

CONTRIBUTORS TO THE COURSE

Just a few of the husiness leaders who have contributed to the Institute training course are such prominent men as

Ldward R Stettinius, Jr. Thomas J Watson Chenman of the Board U.S. Steel Corp Alfred P Sloan, Jr Chairman of the Board General Motors Corp

Major B. Foster nan, Deps of

Pres , International Business Mach Curp E J du Pont de Nemours & Co , Inc

Colby M. Chester, Jr Chairman of the Boar General Foods Corp.

"PORGING AHEAD IN BUSINESS" is an interesting. "PORGING AHEAD IN SUSINESS" is an interesting, helpful booklet. It is yours for the asking Send for it. Measure yourself by it I ook clearly, for a few moments, into your next few vars. Whether or not you will follow the path it points he as matter that you alone must decode

that they can do it within the next few years. Do you believe this? Do you care enough about independence to give us a chance to prove it? Will you invest one single evening in reading a booklet that has put 400,000 men on the road to more rapid progress?

This booklet costs you nothing-and for a good reason. It is worth only what you make it worth. It explains how

for more than thirty years it has been the privilege of the Alexander Hamilton Institute to help men shorten the path to success; to increase their earning power, to make them masters of the larger opportunities in business.

Why Tomorrow Will Be Better Than Today

BETTER houses... better factories better roads and food and clothing. Because with pencil and graph, with slide rule and calculation, the engineer is charting the way is turning visions into realities. He is applying the findings of science to the task of satisfying your needs and wants

Under his hand there takes shape the steel mill or textile mill of the future. Automobiles and overcoats, made by improved methods, will be better, yet less expensive More efficient turbine-generators—and cheaper electric power will lighten the tasks in every home. Improved shoe ma-

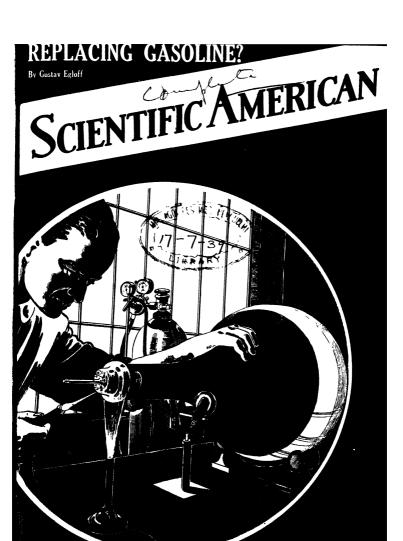

chinery and better and less expensive pairs of shoes

The engineer's application of electricity to every branch of industry has helped to make America the greatest industrial nation in the world -has helped to provide you with the highest standard of living the world has ever known. And General Electric engineers and research scientists, working in partnership, have led in this electrical progress G-E research has provided new knowledge; G-E engineers have put that knowledge to work to make available more goods for more people at less cost.

G-E research and engineering have saved the public from ten to one bundred dollars
for every dollar they have earned for General Electric

90-5DH

CARL SANDBURG

IN A RECITAL OF AUTHENTIC
AMERICAN FOLKSONGS FROM HIS COLLECTION

"THE AMERICAN SONGBAG"

Gallows Song ("Sam Hall")
I Ride an Old Paint
Foggy, Foggy Dew
The Horse Named Bill

Woven Spirituals
The Good Boy
Mama Have You Heard the News?

I'm Sad and I'm Lonely

(Eight Songs on Four 10" Records)

"Never, in our recollection, has the personality of a man come through the mechanism of the phonograph so startlingly true to life as has Sandburg's.

"The vast audience who have heard Carl Sandburg sing these songs at intimate recitals in the colleges and clubs of this country, the students who have studed his poetry, the numberless owners of copies of 'The Americian Songbag' know how personal is his art. For those who have never heard these songs as Carl Sandburg performs them, we can but list the titles and advise that, no matter how familiar the individual song, you will agree that you have never heard the depths of folk music sounded until you have heard them sung by Carl Sandburg "— Musicraft

"Carl Sandburg, famed as a poet, would rather be known as the greatest living singer of these American songs A grateful posterity, listening to these records, may well decide that his choice was right."—Life.

STORY'S SPECIAL OFFER

STORY, America's Literary Magazine, including in its contents the finest short stories available ("Address Unknown" caused a world-wide sensation, and now in book form is a current best seller—twelve of the stories in "The Fifty Best of 'O'Brien's Best'" are taken from STORY), novellas (long stories), outstanding literary comment and reviews, and interesting End Pages, Announces This Special Money-Saving Combination:

For only \$5 you may have a full year's subscription to STORY and the four Sandburg records. The records come to you, safe delivery guaranteed, in a handsome album with Sandburg's picture on the cover. Subscription may be a new one or a renewal. Records and subscription may be sent to different addresses.

Price of the album with 4 Records . . \$4.50

Subscription to STORY for one year . . \$2.00

The Great American Rite-By T. Swann Harding

The Public is Largely to Blame for the Too Casual and Rou-

THE most intricate part of a television receiving set is the cathode-ray tabe, described in some detail on page 28 of this issue and illustrated during one process of manufacture on our front cover. Here the operator, a skilled glasworker, is sealing into the narrow neck of the funnel-shaped tube the "plug" through which pass the wires that form the electrical connections to the internal elements of the tube.

OUR POINT OF VIEW

"Self-Sufficiency"

UNDER the title "In Case of War," 1936, issue, a discussion of those strategic raw materials which this country must import because we have little or none at home and which are absolutely necessary to the proper functioning of our vast industrial empire. The list of these vital imports given in that article totalled more than two dozen at the time of publication. There is today no essential difference in the number and kinds of materials in such a list, yet there has been a momentous change in the picture. Chemistry has provided satisfactory substitutes for some of them, found ways of providing nearer-home supplies of others

In this issue is an article which summarizes startingly the ends to which Europe must go in order not only to the prepare for the operation of motor vehicles during a possible future war but also to assist in the present comonic war. A similar motor fuel problem will not have to be faced by the United States perhaps during the lifetime of present generations, Yet on this side of the Atlantic there are other, no less pressing problems to be faced and solved if we are to maintain our national economy with little disruption in time of an emergency.

A second article in this issue serves to emphasize one problem which we do have—that of supplying rubber, which we must import, to a large number of industries. More important, this article also gives a limit of what we are doing to face this situation. It shows that we, too, have creatiz materials; that is, substitutes for natural products. What people do not generally know is that this business of finding something of native compounding to take the place of scarce or imported necessities is important in its own right. It is this that has changed the puture alluded to above

Synthetic resins are being used now where imported tin was hitherto indispensable; chromium and platinum are giving way to domestic alloying matetials; organic substances are used for rubber, silk, quinine, Manila fiber, and opum; and improved processes are making available hitherto unworkable deposits of low grade manganese ore.

So far, only a start has been made in this drive for a form of self-sufficiency. Yet an enormous effort is being made in this direction, and it can be stated positively that, in case of a future war, we will be in a much better position to supply the materials required by industry than most people imagine.—F. D. M.

Incomparable Promise or Awful Threat?

OR years past, scientific writers have been pointing out the fact that if the energy known to be confined within the atom could be practically and commercially released and employed, there would be power in amounts today unknown. A handful of atoms would suffice to drive a liner to Europe and back, for example. The atomic energy of a piece of coal would exceed that of the same coal burned beneath a boiler by a ratio of a whole billion to one, Such writers have usually hastened to add that there was no prospect of man's ever unlocking these stores of power, and some have hinted that perhaps this was just as well.

Once more the foolhardmess of predicting impossibilities threatens to be demonstrated because, as this is written, physicists are at work on experimentthat seem to contain the possibility if not the probability that the billion-to one power source is at least within view. The uranium isotope 235, when bombarded with slow neutrons, releases inconceivable energy. Simultaneously it releases more neutrons and, if uranium 235 isotope be present in quantity, the result of this trigger effect is a chain reaction of far more than terrible power, Fortunately, uranium 235 is only one hundredth as common in the ores as ordinary uranium 238, else exceedingly dire resultsexplosions of magnitude heretofore unknown-would automatically follow unless proper control were provided.

Here, in this last clause is the question that is worrying the physicists. The minute a new force for man's benefit is found, individual examples of the genus homo begin plotting to use it as a destructive threat or in actual destruction for their own selfish, reckless ends. First impulse, then, among physicists is to abandon the experiments. Second thought shows that this would be merely to abandon them to these self-seekers, the war-makers and world conquerors. The physicist cannot stop. At first it might seem that, by an agreement, all the physicists could simply drop the matter and that this would end it. But the physicist is no more certain in advance whether his discoveries will be a curse or a boon than anyone else. He is a part of the stream of only slightly foreseeable human events. He cannot control his own discoveries, once they are given out, for he is far outnumbered. And if the human race won't leave its new playthings alone, and gets badly hurt, that's its own funeral. In a few years we may have the answer .- A. G. I.

Television Problems

COMMENTS, crutisims, suggestions, questions regarding television have been reaching this writer in increasing of regular scheduled television service in the metropolitan area. Two phases of the subject stand out above all others as being of great apparent interest to a large number of people. The first has to do with the service range of transmitters and the second with the possibility of constructing sets in the home workshop.

The service range of a television transmitter, under present conditions, is severely limited and that's all there is to it. With the extremely high frequencies that must be used to bring television signals into the home the range of the transmitter is practically limited to the optical horizon. Freak reception may be recorded occasionally beyond this area, but such freaks do not alter the situation as far as the average person is concerned. In other words, it must not be expected that the DX nights of early radio broadcasting will be revived in television reception. If you live within the service area of a television transmitter, you can enjoy television reception; if you do not, the only thing you can do is to wait until such service is made available in your locality. It would be useless, for example, for a resident of Texas to purchase a television receiver with the expectation of being able, even occasionally, to receive television broadcasts from New

Television receivers are admittedly expensive. They must be so because of their extreme complexity. This same complexity militates against the construction of receivers in the home workshop, although kits of parts are available for those hardy souls who will try anything once. Just because a person once built a satisfactory radio sound receiver, however, is no indication that he will be able to achieve the same degree of success with a television set. The skill required is far greater than that called for in constructing even a very elaborate sound receiver. Then, too, there is the element of danger from high voltages (kept un-der "lock and key" in commercial tele-vision receivers) that might lead the constructor into serious trouble.

Does all this seem pessimistic? It is not intended to be so, but rather is intended to present the facts as they stand. Television is bound to become an important factor in our daily lives; don't spoil it for yourself by starting off on the wrong fool.—A, P, P.

50 Years Ago in . . .

(Condensed From Issues of July, 1889)

VALUE—"II I gave you a pound of metal and ordered you to make the most out of it, what kind of metal would you select? saked a well known jeweler. 'Gold, of course,' was the prompt reply. I'd prefer a pound of steel,' and the jeweler,' and I'd have it made thair aprings for watches. A pound of such aprings would sell for an even \$140.000."

ELECTRIC CARRIAGE—"The accompanying illustration represents the application of a system of electrical propulsion for common roads, by means of which traffic is designed to be carried on with out employing a railroad track, the steering gear being so arranged

that the wagon will automatically run parallel with the line of the conductors. . . The wagon body to which this improvement is applied is partly apported on a caster wheel, provided the proposed of the forward of the provided of the prov

DEVELOPMENT—"Mr. Ersatus Wiman, on the subject of telegraphs and telephones, in an address before the New York Electric Club, recently said, among other things, that it was a great blessing that the telegraph and telephone were early divorced, because I do not believe that the telephone would ever have been developed to one-quarter the extent to which it has been developed if it had been dependent on the telegraph.

POISON—"According to Mr. Stanley, the arrow poison used by the natives of the Lower Congo district; ir made from a species of reasts found in that locality. The ants are dried, crushed into powder and cooked in palm oil. The exceedingly irritating properties of the poison are summosed to be due to formic acid."

ELECTRIC LIGHT—"Electricity on ships of war is purely an American idea, and was first tried on the United States steamer

Trenton in 1883 ... Soon after the system had been tested the vessel sailed on a three years' cruise, and attracted much attention as the first vessel affoat to be lighted by electricity. The success of the Trenton's experiment practically settled the question in naval circles."

TELEPHONE—"Baltimore will be the first all-metallic circuit telephone exchange in the United States, and we predict that it will be without equal in the world."

JETTY—"The bar at the mouth of the Columbia River, Organ, has been a source of dread to manners frequenting that region, ... Since the commencement of the development of the 'Inland Empte' think the commencement of the development of the 'Inland Empte' or the commence has increased yearly until at has assumed such proportions as to demand radical measures in the way of improving the channels. A project ..., which has been adopted by Congress, contemplates a sungle permanent channel across the har, having the depth of 30 feet at mean low tide ... A rock jetty resting on brush mattreases as to be built from Point Adams ... for a distance of 4½ miles, more or less, as circumstances may require, to a point about three miles south of Case Disappointment."

HEART FAILURE—"The American Analyst thinks it would be an excellent idea if physicians of the present day would invent some other reason for all the deaths which occur nowadays han heart failure. It is difficult for any one conversant with the organs of the human body to understand how any human being can the without heart failure, while the causes of the failure of the heart at death may be very numerous."

STREET RAILWAYS.—"The bill recently signed by the Governor of New York, allowing the street railroad companies to substitute mechanical motive power for horses, is an important one. We hope in time to see it lead to a general use of electric motors on the roads in this est;"

ELASTICITY..."Professor John Trowbridge . . . calls attention to the importance, from an engineering point of view, of making careful photographs of steel and timber at the point of rupture under a breaking load, suggesting that in this way we may learn something important on the much exced question of elasticity."

WORSTED-WOOLEN..."The question is asked, what is the difference between worsted cloth and woolen cloth? The answer is: Worsted goods are composed of wool that has been carded and combed, while woolen goods are made of wool that has been carded but not combed."

A strange sight to an American: a "filling station" for Rome's 85 wood-burning buses. Small furnaces, concealed in the rear of the buses, and charged with blocks of wood out in small sizes (or coal or chargon), generate the gas which the motor uses

Ersatz Motor Fuels

THE dominant note in Europe today is self sufficiency; the dictates of nationalistic forces have made production of all wartime supplies of greatest importance. Under such a régime the economic side of the situation is subordinated to the necessity of masutaning within national borders the means of carrying on war measures in the face of an extensive blockade.

To the army and air forces of a highing nation, motor fuel is almost as vital as man power, and since most of the nations concerned are deficient in oil supplies, the manufacture of sub-titute fuels has been forced to a new high since 1937. The willingness with which Europe accepts substitutes, which permit conservation and storage of gasoline against a possible war, points the way toward operation of all civilian motors on substitute fuel so that military machines may have the exclusive use of all Europe's Desperate Nationalisms Force Use of Native Fuels...To Conserve Gasoline for Possible War...Result: Enormous Net Monetary Losses

By GUSTAV EGLOFF
Director of Research, Universal Oil Products Company

gasolme. This would be the wartime ideal. Eighteen percent of the motor fuel consumed in Europe during 1937 consisted of substitutes for gasoline. The substitution seed range all the way from solid substances such as wood and coal to compressed gases of several kinds. Offhand this might seem to indicate great saving since the cost of imported gasoline is extremely high in Europe as compared with gasoline cost to American motorists. By the use of substitutes, however, Europe but approximative \$235,

000,000 during 1937. This was an alltime high. Yet 1938 showed an increase up to 25 percent of all motor fuel used and a loss of about \$300,000,000 through subsidies and taxes

Americans who have heard much of the plan, in this country, to use alcohol as a blending agent with gasoline, will be surprised to learn that use of power alcohol in Europe is steadily declining. The same war scare that is promoting use of motor fuel substitutes is diverting alcohol to the munitong, industry where

it is a vital raw material. Furthermore, alcobal is essential in wartime for medicinal use, and motors adjusted to use it in peacetime would require costly readjustments to use other fuels when war breaks out. Afready, there are insufficient supplies of alcohol in Europe, so that France and Italy were curtailing its use in 1937, while Germany not only twee reduced the mandatory percentage of alcohol in gasoline but also had to import supplies of it.

Even with declining use, with alcohol constituting only 4.3 percent of Europe's motor fuels in 1937, it cost Europe that vear \$104,040,000 more than an equivalent amount of imported, tax-paid gasoline. Other substitutes made up the remaining 13.4 percent and cost \$130.826. 000 more than imported gasoline. These losses are made up by the direct and indirect subsidies on native motor fuels, by special taxes on imported motor fuels, by partial elimination of taxes on native fuels and the vehicles using them, and, in some cases, by direct payments to operators of vehicles using native substatute fuels. As is the case in any country where any one group is aided by the government, it is the public-each and every individual-who pays, in taxes, the European motor fuel bill for the favored

WOOD, charcoal, coal, and lignite are used to make producer gas in generators on many European motor cars. Compressed natural and mantatural and mantatural and mantatural and mantatured illuminating gases are carried in clumy tanks on some cars. Experiments have been conducted in efforts to utilize acetylene, cracked ammonia, and hydrogen. Hydrogenated gasoline is, however. Europe's primary substitute motor fuel. While this fuel is actually gasoline, it as a manufactured product—from cither coal or carbon monoxide—and is subject to the limitations of factory production.

Hydrogenated gasoline is the only one of the various substitutes which is of possible value to the United States. Small

about 18 cents per United States gallon. When units now under construction and designed are added to those now onerating in Germany, that country's production of hydrogenated motor fuel will total about 17,000,000 barrels per year. In England, the production is about 1,300,000 barrels a year; while France is operating only a small unit producing 110,000 barrels a year. These figures may be compared with the world production of gasoline from petroleum by cracking and distillation totalling 775,000,000 bar-rels a year and it will be seen that only a tiny dent has been made in the problem of supplying manufactured gasoline to supplant that from petroleum.

Combustible gases of many kinds-including natural gas and gases recovered from both hydrogenation processes, from coal carbonization, and from the cracking process—are being used more and more widely in Europe. In Germany, lightweight alloy cylinders have been develop-ed for attaching to motor cars to carry the combustible gas under pressure. These are picked up as replacements in filling stations that dot Germany, or are refilled at the stations with city gas, methane, or propane-butane. It is estimated that there are in Germany 25,000 vehicles using a total of about 250,000 such storage tank cylinders. Depending on the gas used, a given vehicle using two of the tanks will travel on one filling 25, 85, or 225 miles.

The use of compressed gas as a motor fuel requires conversion of vehicles, consisting of the installation of racks to carry the tanks, a regulating valve to control pressure, and a special gas-air mixer in

experimental plants are producing a small quantity of hydrogenated fuel in this country, looking toward the time when petroleum supplies will have become so nearly exhausted as to make neccesary a supplemental supply of fuel. At present cost of production, hydrogenated gasoline 1s-too expensive to use in America. In Europe, this fuel, whether produced by the hydrogenation of coal or of carbon menoxide, is believed to cost place of the carbureter. To make this conversion, the cost may be from \$150 or \$300, depending upon the size and power of the vehicle. The number of tanks upon the vehicle versies from two to eight, depending upon the type of service; passenger buses may even pull trailers to carry the tanks. Each steel cylinder weight 115 pounds empty and 215 pounds when filled with propane-butane at a pressure of 150 pounds by evenuare inch. This set of 150 pounds.

100 pounds of gas is equivalent to 18 gallons of gasoline.

Perhaps the oddest motor fuel used in Europe, from the American pound view, is producer gas from wood and coal. Yet despite the fact that these two raw materials probably come nearest to being plentiful in some countries of Europe. relatively few wholes burn gas made from them. Drastic laws have been passed to promote wide use of producer gas and government subsidies have been granted users, but there are even yet no more than about 9000 wood-burning vehicles. In France, Germany, and Italy they consume annually 450,000,000 pounds of wood. This amount is equivalent, in motor operation, to about 18,000,000 gallons of gasoline.

Some cars are built directly for using producer gas from wood, but more often gasoline types are converted by adding a stove to burn the wood, cooling pipes, filtering agent; tank to collect condensed water, tar, and acids; and sometimes a blower. The cost of this conversion may range from \$300 to \$500.

Gasogenee, as the units are called in Europe, operate by hurning wood, wood charcoal, coal, lignite, or briquettes in a high steet cylunder which may be lined with a ceramic insulation. The fuel is loaded in through an opening at the top and lighted. Air is admitted through an opening at the bottom, and the gases resulting from combustion leave the tank through another opening at the bottom. The combustible gases are cleaned by passing through cooling pipes to collect

At right: A Parisian taxi driver attracts curious bystanders as he loads his wood-burning taxi with a charcoal-anthrerite misture. Below: Motorman's cab and wood-burning gas producer in a French passenger bus. At bottom of page: A German bus which carries compressed gas fuel in trailer tanks

duction of France were used in this manner, it would still supply only 10 percent of the nation's requirements in motor fuel. The reduced efficiency, inconvenence, and delays in saturing and for relatively frequent cleaning are other objections to the use of wood to make gas for motor fuel.

Coal, in several grades, is more plentiful in Europe, and these raw materials, used singly or mixed in various ratios, could be used far more widely than at present in case of a national emergency.

Of the other substitute motor fuels used or tested in Europe, little need be said. In a number of countries, oil is being extracted from shale. This is a substitute, of course, only in the sense that at takes the place of imported motor fuel. In Italy, synthetic ammonia, after being cracked into introgen and hydrogen, has been used as a motor fuel, but its low efficiency and high cost are factors militating against its general adoption. Activity of the control of the

LEARLY, gasoline would serve all CEARLI, gassauth more efficiently than these expensive substitutes and semi-substitutes, even under the prevailing strained economic conditions. Purely from a military standpoint, the huge loss of \$300,000,000 brought about by their use might be used to better advantage in purchasing and storing petroleum for wartime needs. The reason civilian populations will tolerate this loss is probably due to the fact that the burden is relatively small because of the smaller number of cars in proportion to population. In all of Europe, with a population of over half a billion people, there are only 8,189,335 motor vehicles as compared with 30,000,000 automobiles for the United States; or one car for every 63 people as compared with our one car for every five people.

water, tar, and acids. A dust catcher and a filtering chamber collect the colloidal particles of dust from the gas which is forced by a blower into the motor.

Despite its many disadvantages, the wood-burning motor has one point in its favor: the filling station can be any wood pile where good, air-dried wood is available. However, it takes about 25 pounds of wood to give the same distance performance as a gallon of gasoline. Many

wood-filling stations are scattered over France, Cermany, and Italy and from them 30 to 60-pound packages of wood may be purchased. The cost is low, but any comparison with the price of gasoline is fictitious because of the several subsidies and taxes that enter into the question. Furthermore, it can be confidently said that gasogene vehicles will never prove a satisfactory saver of petroleum products; if the entire annual wood pro-

Lies-Truths

A murder suspect being tested on the Polygraph he detector by the author. A rubber tube encircling his chest and another on his arm transmit fluctuations in his breathing and pulse to the instrument, making record on a moving strip

VICHITA, Kansas, sometimes is called the proving ground for the Keeler Polygraph or so-called he detector, for it is there that more persons are tested annually with Polygraph deception technique than anywhere else in the world.

The Wichita instrument is owned and operated by the Police Department Each year more than 1300 persons submit to he-detector tests, because of suspected criminal activities or because it is thought that they may be closely connected with certain criminal offenses Each test is accurately and painstakingly recorded and statistical data are compiled to measure the instrument's value in police work and to determine its accuracy and inaccuracies.

Since scientific lie detection is comparatively new to police, and since it has only recently branched out into the commercial field, statistical data have been more or less limited and the technique of detecting deception has had to withstand the usual doubts and prejudices met by things new. The first question aroused in the minds of those in authority is: "How does it work?" Usually this question is followed closely by another: "What dependence can I place in such a procedure?"

The answer to the first question, of course, deals with the mechanics of the instrument, the theories or facts upon which its operation is based, and the procedure used in applying the technique. This question was comprehensively answered in my article, "Scientific Detection of Lics," which appeared in this magazine in June, 1937, and will be given only a short explanation here

Polygraph deception technique is based on the fact that certain emotional disturbances take place within the body during attempted deception. These disturbances, when recorded, are discernible in the blood-pressure and respiration of the individual taking the test. The Polygraph instrument is so constructed that blood-pressure and respiration are recorded simultaneously on mov-

The second question can be answered only by application of the acid testresults. Heretofore, sufficient statistics have not been available, and therefore a comprehensive and factual answer could not be given. Now, however, with 4000 recorded examinations on file and a complete research of cases made during the

ing paper during the entire examination.

years 1936, 1937, and 1938, it is reasonably safe to state that the he detector is playing a most important part in weeding out the guilty from the large number of persons whom police find it necessary to investigate

Segregating the 4000 examined subjects into units of "truthful" and "untruthful," it was found at Wichita that 3026 were able to produce "clear" records-those in which no deception was displayed. Of this number, 1690 were transients or vagrants picked up in the railroad yards or found lottering about the city streets. They were questioned about crime in general, and usually were released upon the completion of records which indicated that they had not committed any crimes and that they were not "wanted" by other authorities.

ON the other hand, 974 of the 4000 produced records which indicated that they were not telling the truth. From this number, police were able to secure 537 full confessions to the crime under investigation. Subtracting this number from the 974 in the supposed "untruthful" group, there still were 437 to be disposed of. Of this number, 287 were released because complainants refused to prosecute or because sufficient evidence to prove guilt was not obtainable. The remaining 150, police took through the courts. Of this number, 112 were convicted, 34 were acquitted, and four cases still are pending.

The foregoing figures, reduced to a percentage basis, show that 55.1 percent of those whose records indicated deception confessed their crime: that 74.7 percent of those whose records did indicate deception, but who did not confess. were successfully prosecuted in court;

THE he detector described in the accompanying article is one of four types discussed in The Journal of the American Medical Association (Chicago, Jan. 29, 1939, page 3541. Where do he detectors stand in general? This is largely a matter of opinion. One opinion, on the conservative side, is stated by the medical journal named above, which finds that many of these machines are being exploited by non-medical men although they involve the most complicated torensic clinical principles, and that sometimes instruction is too brief. The same journal recommends the tollowing books on the subject: "Legal Psychology," by H E. Burtt; "Lying and Its Deteclaboration with Geo. W. Haney and Leonarde Keeler; "The Psychology of Feeling and Emotion," by Christian A. Reich-smid; "Trial Technique," by Irving Goldstein; "The Lie Detector Test." by William Marston; and "Scientific Methods of Crime Detection in the Judicial Process." by J. Edgar Hoover. The Editor

also that approximately 3026 persons, who were either suspected of crime or came under police observation, were spared the necessity of long incarcerations to permit the police to check up their many-angled stories.

During the accumulation of these records 31 persons, because of mental or physical abnormalities, produced records which were considered uninterpretable by the operator, Otherwise stated, 99.9 percent of all persons examined were able to produce records upon which a definite and immediate decision could be made.

Space will permit the discussion of only a few cases, hence random records have been selected. Take, for example, the graph produced by a young man. A salesman had parked his automobile in the down-town district, hidden a bag of money in the glove compartment, locked both the glove compartment and the car doors and gone about his business. Returning some two hours later, he found the car broken open and the money gone. Later in the day police picked up this suspect. The young man vigorously denied any knowledge of the theft and was requested to submit to

Now that the Lie Detector Has Been Used by the Wichita Police for Three Years, How Successful Has it Proved? . . . A Progress Report

By THOMAS HAYES JAYCOX Polygraph ("Lie-Detector") Operator. Police Department, Wichita Kansas

Polygraph deception test technique. The graph below shows a "close-up" of the subject's record where he was asked questions concerning the stolen money. Notice the violent deviation from the 'normal" in both the blood-pressure (lower part) and respiration (upper part). Immediately upon completion of the test, the graph was explained in detail to the lying young man. He confessed and led detectives to his home, where the stolen money bag had been rached

The lower graph presents the reaction m a general investigation where police had charged no definite crime against the subject. These tests are given to hobos, vagrants, and to known criminals who are checked up from time to time. The operator simply goes "fishing" with his subject and often the results are more than worth the time and effort expended

- 9 Have you stolen anything during the past year?
- 10 Have you answered all questions truthfully?

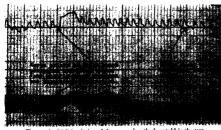

In a typical instance using these questions two young hobos were brought in for tests shortly after they had alighted from an meoming freight train. Both young men steadfastly insisted that they had never before been arrested and that they had committed no crimes. But their Polygraph records had an entirely different story to tell. Notice in the graph the responses in blood-pressure and respiration (shown by arrows) at point 4, where one of them was asked the fourth question, "Have you ever committed any erimes and not been caught?" Notice how similar reactions were displayed at points 5, 6, and 9, corresponding to the respective numbered questions Obviously, the young man was lying when he answered negatively to these questions. Interpretation of his reactions indicated that he had committed a crime and that the crime was burglary of a house or store, as shown by his answer to question 5. He was wanted by the authorities, or thought he was (shown in question 6) and he had stolen something during the past year (question 9).

With these deductions the operator proceeded to question the young hobo, and soon the facts began coming out. When apprised of his reactions, as shown by the instrument, and when their meaning and reason were explained to him, the hobo confessed. His home, he admitted, was in an adjoining state. He and his companion had left there only the day before. Just prior to their leaving, they had broken into a dwelling house and stolen a pistol. The pistol was neatly hidden in a roll of clothing he had been carrying under his arm.

These two cases, extracted from the 537 confession cases previously mentioned, do not by any means tend to reflect that the lie detector is valuable only in minor thefts or lesser crimes. Among the 4000 cases now on file are 52 murder investigations, one of which is the wellknown Wiant case. To the he detector goes the credit for "cracking" this strange enigma and searching out the murderer from among nearly 50 suspects, as well as locating the murder weapon.

On the other hand, the he detector is not a panacea for all criminal ills. It is simply one of the many tools used in scientific crime detection and, like the doctor or physician, the operator is not immune from an occasional misinterpretation of the symptoms.

Yet with the 55.1 percent confession rate, and the successful prosecution of 74.7 percent of those who refuse to admit the truth, it is safe to assume that the lie detector, in police science, will average a high score in precision and accuracy. This assumption is true, however, only where a skilled and well-trained operator is conducting the tests. The instrument in the hands of a novice would be much like calling in a truck driver to diagnose some physical ailment-the recipient of his diagnosis would suffer.

The graph which incriminated the money bag thief, as told in the text

A questionnaire is used which includes nearly every type of crime listed in the statutes. For example:

- 1. Is your home in Wichita?
- 2. Do you live in Kansas?
- 3. Is this the month of 4. Have you ever committed any
- crimes and not been caught? 5. Have you ever broken into a
- house or store for burglary? 6. Are you wanted by the authorities
- anywhere? 7. Have you ever held up and robbed
- anvone? 8. Have you ever stolen an automobile?

Breathing and blood-pressure fluctuations of a hobo under questioning

THE FUTURE OF NAVIES

NEXT in importance to the capital ship discussed last month comes the aircraft carrier, that extremely vulnerable floating aerodrome the existence of which in wartime is looked upon as hazardous, but which many naval officers regard as likely to become as important as the battleship.

Carriers: Since the World War. progress in carrier flying has been such that landing accidents are very rare, and all the elaborate arresting gear has been discarded. Very long and wide flight decks are still necessary-since in rough weather the pilot has to land amidships where the ship's motion is least and yet the plane may have a sufficient runwith ample beam so that an error in judgment, side-slip, or a rolling deck do not lead to a side crash. But "the bigger the ship the better the carrier" is no longer an accepted axiom, and both small and medium sized vessels are now being built instead of those of maximum dimensions so favored at the time of the Washington Treaty. A limit of 33,000 tons displacement, with guns no larger than 8-inch, was then agreed to, these limitations resulting in the U.S.S. Saratoga and Lexington and the Japanese Kaga and Akagi-immense vessels carrying cruiser armaments and a considerable weight in waterline protection. When the Treaty came into force, Britain had just completed the Hermes of 10,850 tons only, steaming at 25 knots and having an official complement of but 15 planes, while Japan had passed the 7470-ton Hosyo into service-a vessel of original design housing some 25 planes and capable of 25 knots.

In the Hermes, the deck was of sufficient width to allow for the funnel to be brought up through an island superstructure which an experimental canvas erection on the Irgus—a clear-deck ship with side smoke ducts discharging at Second of Two Parts . . . Carriers, Cruisers, Destroyers, Submarines . . . Ships Building . . . Dimensions, Armor, Armament . . . Comparisons

By OSCAR PARKES

the storm—had shown to be a practical storm—had shown to be a practical production of the disadvantage of hangar heating, with restricted housing accommodation, experienced in both this ship and the Furinus. But in the Hasyo, the dick was too narrow for this arrangement and recourse was had to small hinged side funnels which could be lowered to a horizontal position during flight work, as in the U.S.S. Langley, converted about two years after the Japanese ship was designed.

Åt the present time, both systems are in favor, while in the matter of size a considerable latitude is observed, depending upon the specific service for which the carrier is designed. Cost and vulnerability militate against maximum dimensions and the latest designs range from 10,000 to 23,000 tons with a wide variation in features dictated by national requirements.

THE huge 27,000-ton Kage and Akagi, of Japan, have recently been reconstructed, the alterations including a lengthening of the flight deck by some 150 feet so that it now extends to the lower, shifting of the forward 8-inch guns formerly carried in two turrets on the lower flight deck to casemates in line with the other six such guns on the main deck aft; addition of many machine guns along the topsides; and, in the case of the Kage, an alteration in her funnels. Formerly she had great trunks from the furnace uptakes amidships,

along the outsides of the hangar, discharging as bell-mouthed vents aft; these have now been replaced by a brace of curious side trunks amidships below deck level, one of which curves up and the other down—a system tried out and retained in the Mags. During flying operations, the down trunk is used, the furnace exhausts being discharged away from the ship by an admixture of pressure steam.

In the Ryuzyo, built between 1929 and 1933, an attempt was made to produce a carrier of small displacement but able to house 25 planes. Thus upon a hull 548 feet long and drawing only 151/2 feet, with a beam of 601/2 feet, a huge hangar was erected with six pairs of 5-inch guns and numerous machine guns along the topsides. She also had a pair of side funnels amidships and made 25 knots on trials. But, in practice, she has not fulfilled expectations, having proved a bad sea-boat; hence, in three later carriers, Sorvu (completed 1938), Hiryu (completing), and Koryu (building), some 3000 tons have been added to the displacement, yet the general characteristics of the Ryuzvo are retained. While in the Ryuzyo, the ratio of length to beam is 9 to 1 and beam to draft 4 to 1, in the Soryu it is 10 to 1 and rather more than 4 to 1, respectively, her dimensions being 6881/2 by 681/2 by 161/2 feet.

Most Japanese types appear to run to abnormal dimensions, and these ships seem to be asking for trouble. Compare

The 23,000-ton, British Illustrious, one of five now building, mounts eight pairs of A.A. guns and six 8-barreled pom-poms

Japan's 8500-ton cruiser Kumano mounts five triple 6-inch turrets. Torpedo tubes are in curious ports by the main mast

them with the U.S.S. Wasp, of 14,700 tons, which is of the same length as the Soryu but has an 81-foot beam and draws 20 feet! Moreover, the Wasn's length is "water-line" whereas in the Japanese ships it is understood to be "between perpendiculars," so that the overhang of the stern from judder pintle to counter must be added-probably another 30 feet. Such a long, narrow, and shallow hull, surmounted by a great wind-trap of hangar, does not appear to be a very happy conception, although the Japanese designers aim to increase stability by a marked flaring of the hull for three quarters of its length and the fitting of gyro-stabilizers.

These 10,000-ton Japanese carries are reported to carry 30 to 40 planes, have a designed speed of 30 knots, and mount 12 5-min gams. More seemly looking than the Ryuryo, their sides have been spared that bookage of sponsons, platforms, pillar supports, and cluttered control positions which disfigure that ship; the funnels are small trunks on the starboard side only. Apart from a small patch of armor over the engine and boiler rooms, they are unprotected against surface attack although well armed for sky defense, and well represent a type of small carrier which has many advocates.

In the Ranger (completed 1934) the Construction Bureau of the U. S. Navy provided accommodation for 75 planes in a ship of 14,500 tons with a speed of 29 knots and armed with eight 5-inch guns. An island superstructure with bridges, control positions, and a light tripod mast was placed on the starboard 'midships, with three hinged funnels on each side toward the stern. The leeward set are used to keep the deck free from smoke and heat eddies. Following her came the Enterprise and Yorktown of 19,900 tons each, carrying over 100 planes at 34 knots. These are generally enlarged editions of the Ranger but with a much larger island built around a most imposing funnel as in the Saratoga. se ships have catapults on the flight and hangar deck forward so that aircraft can be shot off without having to raise them to the upper flight deck. Protection is limited to an armosed deck and some gine rooms, sufficient only to keep out small projectiles since their metier will be to avoid action and rely upon a protecting screen of ships.

A return to smaller dimensions has been made in the Wasp and Homet, now building, which are 14,700-ton vesselshousing 75 planes. Presumably cach will have an island superstructure and funnel to stat board, as this appears to be the best solution of the furnace uptake problem when practicable. There will be the same armament of eight 5 sinch guns with 30-odd smaller machine guns; and they again are intended to be carriers pure and simple in distinction to the new Gruman reafit.

THE German Graf Zeppelin, recently launched, and "B," still on the stocks, were laid down in 1936 and are Germany's first attempt at carrier construction, which was forbidden to that country under the Versailles Treaty. Actually, so long as her naval operations were confined to the Baltic and North Sea. she had no need of such craft, as shore stations could provide the formations required in these waters. Neither was transport required to overseas stations, as she has none. Hence, when it was decided that a ficet air arm should be built up, the question as to what type of carmer was needed called for special considerations. Freed from coast defense duties, the new fleet was intended for the high seas, and guerre de course was to be the main function; hence carriers would have to be specifically designed to that end. They might act in company with the big ships, or on their own after being escorted through blockaded areas either by surface ships or submarines or both. Yet when attacking convoys, they would be compelled to face enemy escorts of certainly cruiser tonnage; to fight with any prospect of success, a cruiser armament, in addition to a heavy sky defense, would be a first consideration. To keep out the enemy's shell and to localize hits means armor and subdivision of the hull proper by heavy plating, which absorbs a lot of tonnage; high speed under economical power sans a long ship, with adequate beam and draft for proper sea going qualities in the Atlantic, and a high freeboard. There would be no call for a very large number of planes to be carried, while a small target would be a sensible advantage. Therefore hangar space was limited to 40 planes. Working upon these desiderata the Germans have produced a new conception which is bound to influence naval warfare very considerably.

Displacing 19,250 tons, the Graf Zei prlin is 820 feet long between perpendiculars-about 70 feet longer than the Yorktown (p.p.) -881/2 feet in beam, and 181/2 feet draft. The hull is simple and plain, four decks high, surmounted by a two-deck superstructure along which runs the flight deck. This falls short of the bows as in the Ranger, so that a hangar catapult is probable, apparently there are to be catapults on each side of the flight deck forward. Sixteen 6-inch guns will be mounted, two aside in deep embrasures up forward and again in sponsons towards the stern, with the rest-so it is reported-in twin turrets fore and aft of the island superstructure as in the Saratoga. These guns will all have high-angle elevation. Ten 4.1-inch and 22 smaller anti-aircraft guns make up a splendid all-purpose armament, fitting her for cruiser duties or for heating off air attack.

Forty planes will be carried by the Gral Zeppelin and "B" and the designed speed is 32 knots. No details as to protection are available but launch photos show an end-to-end armor belt and their hulls will probably be built on cruiser principles. From these details, it will be seen that, when operating on the trade routes, these two ships will introduce novel and difficult problems in the matter of counter measures.

Incidentally, it has been disclosed that Incidentally, it has been disclosed that of mine-laying, the mines either being dropped from the air at low altitudes or released from sepalanes riding on the surface. The torpedo planes have 16-inch and 17.7-inch torpedoes loaded with 330 pounds of T.N.T. and 400 pounds of Novit, a new explosive. These are released at 20 to 50 feet above water, and both types have a range of 2200 yards at 45 knots with gyrocoopic adjustment so that they run in straight tizens or

Setting the destroyet pace, France's Mogador, a "cruiserette," mounts eight 55-inch guns and makes 39 knots

spiral courses. High explosive bombs vary from 110 to 100 pounds, and there are armor-piercing bombs, gas and phosphorus bombs for use against personnel, and delayed-action 110-pound bombs for antisubmarine work.

Having had an experience of someting like 20 years in the design and construction of carriers which has covered a wide variety in types, and every opportunity in the matter of trial and error over a wide field of experimentation in design and cupiment, the Brishs Admirally has seen fit to revert to a typeen larger than the Courageous which, a few years ago, was considered as an 'out-size' not likely to be repeated The 22,000-ton Ark Royal has recently been passed into service and five more about 50 feet longer and 1000 tons heavier are now on the stock's

This latest type of carrier is 800 feet ong over all. 94 feet beam, and 23 feet mean draft; that is, about 88 feet shorter and 11 feet narrower than the American and 11 feet narrower than the American aircraft and an armament of 16 4 5-inch dual purpose guns, a sky defense of swindlipe pompons, and eight multiple machine guns. According to present standards of arming, this is a very heavy equipment, but could only be used against destroyers and aircraft.

The effect of eight-barrelled pom-ponus gainst destroyers has yet to be experienced, but in the opinion of torpedo officers they will have a devastating offect, being able to pierce plating and boilers, gun shi-das, and piping with such an overwhelming fusilade that no previous experience with rapid-fire guns can a multiple pom-pom battery open fire a multiple pom-pom battery open fire upon radio-controlled airorat at such a height that they could be followed only with a powerful pair of glasses. There was a thunderous rolling—not the expected staceto of machine guns, but a poeted staceto of machine guns, but a

continuous roar. In a few moments, a plane was twisting and tumbling down from direct hits, and was retrieved riddled!

The 45-inch is a new caliber, fust mounted in the 1th Royal, which would appear to be rather an unnecessary substitute for the 47-inch. These guns are paired behind shields in side sponsons just below the level of the flight deck and have almost uninterrupted ares of sky fire.

Sixty planes are carried in the Ath Royal, the hangars being arranged on two decks with three lifts transporting them to the flight deck. At the bowwhich flares out to almost the extreme width of the deck-there are two catapults, with the deck between them ramped down to give a clear runway. The stern is quite an extraordinary structure with the end of the flight deck carried aft far beyond it as a fan-tail to facilitate landing. Apart from having a plated-in forecastle and stern section, the Ark Royal resembles the Courageous and. being actually a deck higher than the Saratoga, presents an immense target. Otherwise, she has no special points of interest in general design.

The French Joffre and Painleve, now building, are to be of 18,000 tons and are reported as designed for 32 knots. No details are as yet available and they will not be ready until 1941.

Italy has no need for carriers, as the Mediterranean can be covered from her shore stations.

Cruisers In designing her cruisers, Japan has sought to compensate for an agreed interiority in numbers, under the Naval Treaty, by installing superior armament in each ship. This has meant, in general, an increase in length to accommodate more turrets, with additional beam to give stability, and a necessary reduction in draft to keep displacement within Treaty limits. Her low free-board hulls, well sheered forward and tailed down aft, flared at the lows and along the water-line, surmounted by wend tower masts, a serifed line of turrets, and wildly raked and twisted funnels, present profiles which cannot be mistaken

In the ax ships of the \$500-ton Mogamus class, commence between 1981 and 1985, was mounted an armament of 15 of meth and eight 5-incl anti-streaft gons, with 12 torpedo tubes and two wing catables, all of which, in conjunction with a long center-castle and considerable to hamper in the matter of bridgework, made the first of the class unsatisfactors, and the first of the class unsatisfactors and ridama, will carry only 12 6-inch guns, and have been considerably modified in other ways in order to regain the first consideration of all warships—sea egoing abilities.

Five other cruisers are also reported as being under construction. These are 7000 tonners and by Japanese standards could carry 10 6-inch or a greater number of 5.5- or 5-inch guns. The 100pound, 6-inch projectile has always presented a handling difficulty for light weight Japanese seamen, and this caliber was retained only because of the adoption of power-loading. But, since power in place of human energy means a great increase in both cost and displacement, a reversion to a smaller, faster firing, man-handled gun, which is almost equally efficacious against present-day featherweight hulls, is probably being considered in Japan for the new 7000ton ships as it is in Britain for the Dido class.

Such cruisers would make admirable commerce raiders or convoy guardians—and it must be remembered that, in wartime, Japan will be vastly concerned with the maintenance of communications between her ports and the mainland of China whence all supplies of necessary minerals will be drawn. Four 8000-ton light cruisers were in cluded in the 1937 United States program and these Atlantas are to carry 12 febring smooth only 47 calibre as against the 53-caliber. 6-inch guns of only 47 calibre as against the 83-caliber. 6-inch guns in the Onnoha, the shorter proceed being a dual purpose jun for use against sea and air targets and general design it as believed that they will follow the Brooklyn lay-out with only two turrets forward and two aft, each lousing three guns. Their commencement has been delayed until this year and they are not likely to be ready until 1942.

In England, at present, there are 21 light cruisers under construction, of which the Edinburgh and Belfast are en larged editions of the 9100-ton Southampton class. They carry the same armament of 12 6-inch guns but the after turrets are a deck higher and the boilers are moved 50 feet aft to bring the catapult between the fore funnel and the hangar. Considerably more interesting are the nine Fin class of 8000 tons, but also armed like the Southampton and steaming a knot faster-the first British cruisers carrying an adequate gun power for their tonnage to be built since the War. In the four triple turrets are 12 6-inch guns, with eight 4-inch anti-aircraft guns amidships and multiple machine guns on top of the hangars each side of the forward funnel. There is a patch of armor amidships over the engine and machine rooms, with continuations fore and aft along the waterline 1 to 5 inches thick, with 2-inch armor on the turrets, so that these ships have a very fair measure of protection. Speed will be 33 knots with about 1700 tons of oil fuel

The 10 ships of the Dido class, of 5450 tons each, represent a small, cheap, and well-armed type which can be built in quantity—a very necessary qualification for a cruiser design. They are slightly—larged editions of the Arethuse—which carries six 6-inch guns and is not very favorably regarded. In the new ships, a

larger armament has been achieved by the introduction of the \$2.55-inch gun, ten of which are mounted in five twin turrers, three being forward on stepped levels and two aft so that sax guns can fire ahead and four astern with wide arcs on each beam. Naturally, such ships can be only lightly protected, having Jinch gunlouse armor and 2-inch plates amidships, plus the usual armor deek below water. With engines of about 70,000 horspower, the designed speed is to be 33 knots, now a standard British figure for cruisers.

There are under construction three medium size French cruisers of the De Grasse class, which will be more or less replicas of the British Fin-8000 tons, carrying 126 inch guns in four triple turrets, eight 3 5-inch anti-aircraft guns, and four planes. No details as to protection have been issued, but these ships should be almost as well armored as the Gloire class recently completed, with 3 to 41/2inch plate over the engines and boilers, 21/2 mch decks, 51/2 mch on turret faces, and 2-inch sides. Within recent years, France has been obtaining very good value for her displacement in all classes, and the De Grasse promises to be an excellent investment

P to now, the Treaty has limited Ger man cruise displacement to 6000 tons and 5 9 inch guns, but in the vessels now building, her constructors have gone to 10,000 tons and 8-inch guns for the Blucher and Seydlitz classes and 7000 tons for a group of medium size mountmg 5.9 inch guns The Blucher and Admiral Hipper are 640 by 70 by 151/2 feet, compared with 588 by 6134 by 191/2 feet of the American Astoria, and will carry eight 8-inch guns in four turrets with 12 41-inch guns and 12 torpedo tubes There will be one catapult and three planes, with hangars amidships. A high speed is not aimed at but with the new, very high pressure boilers, which require about two thirds of the normal hull space, a speed of 32 knots is expected. Launch photos show, from first to fourth turrets, a main-deck belt which is said to be 5 inches, with light bow and stern continuations—in which case they will be the hest protected of the Washington cruisers affoat.

The second group, Prinz Eugen, Seydlitz, and "L," are 6541/2 by 71 by 15 feet, being longer, broader, and with slightly less draught for the 10,000 tons. A few months ago the writer was informed that the Blucker class were being changed to nine 8-inch guns, but as the name-ship is retaining her original armament, it is possible that the Prinz Eugen trio will carry the heavier armament in three triple turrets. It is worth noting that in these ships the Germans have increased beam and diminished draught beyond even the Japanese ratios, and their sides are markedly flared amidships as well as at the extremities, so that, as sea-boats, they would seem more suitable for the North Sea than the Atlantic.

Of the four 1000 tonners, nothing is known except that they will probably carry mne 5 yench guns Blacher and Hipper are to be completed this year but "M" and "N" 10000 tons were not laid down until 1937 and 1938, and "O" and "P" are to be legan this year, so that none of these may be expected to join the service until 1940 or 1941.

Since the completion of the two Italian Garibaldis in 1937, no cruisers of large or medium size have been laid down, but a new type of fighting ship has been evolved in answer to the French 2884ton Mogador class which might be called "cruiserettes." These 12 vessels, of the Regolo class, are enlarged destroyers, or scouts, of 3362 tons armed with eight 5 2-inch and six anti-aircraft guns and eight 21 inch tubes, engined with 120,000 horsepower for 41 knots. They are the first warships to have a designed speed of over 40 knots. Their dimensions are: 114 by 14.7 by 13 feet so that they will be shorter, beamier, and shallower than

The British 8000 ton Fiji class of cruiser: 12 6-inch guns, good armor protection. Hangars beside forward funnel

Britain needs a host of small escort vessels, such as the Black Swan, for convoy purposes

the French ships, assuming that the length is between perpendiculars. They are essentially Mediterranean ships, able to make a very high-speed gue non torpedo-attack with weapons of cruiser caliber, but without the sea-going qualities of a cruiser or her radius of action At present, they mark a very interesting link between the cruiser proper and the destroyer—an upto-date model of the "scout" which has appeared sporadically in most naves at one time or another.

Destroyers: As already noted, the line of demarkation between cruisers and destroyers has now almost disappeared The French Mogador mounts eight 5.5inch guns and 10 21-inch tubes and, with 90,000 horsepower, has exceeded her 38 knots. With guns able to exceed 25,000 vards with a maintained fire of 16 rounds a minute, she is a most formidable craft. The French now possess 32 ships of her general type. They are employed both in the Channel and Mediterranean and have led to the Germans enlarging their destroyers to 1811 tons, to carry an armament of five 5-inch guns in single mounts and eight 21-inch torpedo tubes, and to steam at 36 knots. Thirty ships of the German Von Roeder and Maas classes are now built or completing. These have been countered by the British Tribal class-1870 tons with eight 4.7-inch guns and only four 21-inch tubes - - in which torpedo equipment has been sacrificed for gun power As destroyers proper, the British have 14 of the Javeun class building and seven of the Lightning class recently laid down, the former being of 1690 tons and the latter of 1920 tons, with a common armament of six 47-inch and eight to ten 21-inch tubes. Just how the extra tonnage of the "L" class is to be utilized remains to be seen-probably in increased anti-aircraft

For many years the Japanese have been in the forefront in destroyer design and since 1926 have, year by year, been adding to their flotillas heavy-weights carrying five and six 5-inch guns with six or eight tubes and able to steam at 34 knots They were the first to give gun-house protection with high angle mounts, and to protect their torpedo gunners by shields. They also developed an exaggerated form of bridge, crowned by a heavy range-finder, and generally piled on topweight until the capsizing in 1934 of the Tomoduru (afterwards salved) led to a general criticism of this trend in design and a return to less extreme proportions in hull and curtail-ment of superstructure. In the eight units now building in the Kurosio class of 2000 tons the Japanese have followed the French and Italians in merging the destroyer with the light cruiser and producing a "cruiscrette" carrying eight 5-inch guns and with 34 knots speedwhich is well below what the United States and European Powers deem necessary for this type. But with an armament almost equivalent to that carried in Italian and French vessels of some 900 to 1400 tons greater displacement, they can afford to dispense with that extreme speed suitable for Mediterranean tactics and conditions; for Pacific purposes they should be compared with the U.S.S Somers, of 1850 tons, mounting eight 5-inch guns and twelve tubes, steaming 37 knots, and carrying 500 tons of fuel.

Following the 12 Maury class destroyers of 1936 (U.S.), come the 12 Sims and 16 Benson classes now under construction—the latter being of 1620 tons and generally resembling the standard one funnel Maury class but with six 5inch guns in pars in place of four singles, and the extremely heavy torpedo armament of 16 tubes, of which eight fire on each beam. American designs favor the practice of stowing all torpedoes in their tubes on deck rather than carrying half the number of torpedoes on the center-line and keeping spare ones below deck.

Submarines and Auxiliaries: As regards submarine construction, no departures from the orthodox designs have been produced by any Power, although it is reported that a Russian boat of very large size—over 3000 tons by estimate—has been seen in the Black Sea.

The British, faced with the necessity of excorting a vast overeas traffic, have steadily added small escort craft to ther Home and Dominion navies, of which the Black Stean is the latest sample. Of 1250 tons, she mounts four twin 4-inch dual-purpose guns and, with 3600 horse-power, will steam at 19½ knots. She is designed to accompany a convoy through the submarine and aircraft zone. The earlier British escort vessels were very poorly armed, being first intended to be mine-sweepers, but are now down for re-armanent with six or eight 4-inch guns.

Hosts of small craft—minelayers, motor torpedo boats, and so on—are being added to the European navies, but space precludes more than their mere mention. These brief descriptions of the capital ships, carriers, cruisers, and torpedo craft being built by the Powers give some indication of the tremendous activity being devoted to piling up offensive and defensive squardons in preparation for the hostilities now threatmend through territorial demands by Germany and Italy with Japan at the Far Eastern end of the "Ata;"

AIRPLANES, UNLIMITED!

THE flying machine, in an age in which automobiles roll off the assembly line like shelled peas into a basket, is still hand made. In some stages of assembly, it takes two men four hours to rivet a single square foot of a metal plane's surface. In peace time, this deficiency of our most modern transport

and military device is a machineage paradox; in war, it might be a calamity. For years our air corps officers, aircraft designers and builders, and avastion experts, resenting this production lag, have been praying—more fervently than ever since Munich for some method of producing planes as rapidly as automoboles.

Their prayers seem about to be answered. A new technique, developed primarily by Col. V. E. Clark. veteran designer and our Army's chef eviation enginerer during the World War, and secondarily by Dr. Leo Hendrik Backeland, the father of modern plastice, with the co-operation of Crand Rapids, makes possible (unless all signs fail) a practically unlimited supply of stout, cheap, fast airplanes.

For a year and a half a mystery ship, cream-colored with a vermilion stripe, had been haunting eastern airports from Florida to Quebec, undergoing all sorts of weather, as well as static, impact, and vibration tests. Then, in the course of a Congressional monopoly investigation last winter, Dr. Backeland's son, George W. Backeland, a World War aviator and aviation enthusiast, under fire of a quiz into patent relationships in that giant industrial stripling, plastics, digressed from his testimony long enough to reveal the existence of a laminated plastics plane fuselage which he said could be molded and made ready for the assembly line in two hours, half the time needed to buckle on a single square foot of the present airplane's skin. This was the cream and vermilion "Clark 46." Headlines flared briefly, but Colonel Clark, returning from Europe, squelched the sensation by wireless from his ship at sea. Only now, after months of gruel ling tests, does he feel that his plane's Molded Fuselages and Wings Make Possible Mass Production . . . Plastics Employed . . . 36,000 Planes a Year . . . Tremendous Wartime Significance

By FORREST DAVIS

A hint of the future: The fuselage of this plane is molded from laminated plastics in two shells, can be manufactured economically in mass production, has been subjected to severe tests

performance justifies a public report on its nature and implications. This report I am authorized to make.

HOWEVER the January revelation struck the average newspaper reader, it was no news to rival designers, to builders, plastics researchers, or the National Advisory Committee for Aeronautics. Nor did it surprise the air ministries of certain European powers apart from the Rome-Berlin-Tokyo axis. Insiders here and abroad knew that Clark, a distinguished designer who, among many accomplishments, devised the airfoils, or wings, for Lindbergh's Spirit of St. Louis, had been working at Hagerstown, Maryland, on the mass-production problem. Some even recalled that during the World War he instigated experiments on a molded plane; an attempt which was abandoned after the Armistice because the technicians had been unable to form plywood in permanently smooth compound curvatures and because the adhesives then known failed to protect wood from deterioration.

Few doubted Clark's eventual success. Here was no eccentric, long-haired inventor, but an able acronautical engineer rated high in Wall Street as well as in his profession. His backers, since he tackled the big job in 1934, include some of the most noted industrialists and financiers in the country. Furthermore, a general feeling existed that the time was ripe for fundamental advances in the laggard art of airplane fabrication. If Clark didn't lift the curse of Adam from the industry, it was felt, some one else would and pretty soon. New, synthetic resins brought out by the plastics laboratories had given aviation, as well as a host of other crafts, novel materials and tools.

Early planes were contraptions of doped silk, spruce strips, wire, and bamboo poles. The war brought plywood or veneers bound with animal or casein glue. Plywood was, and still is, unsatisfactory, since it is virtually impossible to protect

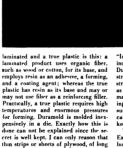

Left: Side view of the "Clark 46," showing the sleek lines of the molded plastics fuselage. In this model, the wings are of plywood, to furnish compari sons between the two materials under operating conditions. Below: A close-up view of the molded fuselage, showing absence of rivets and other projections

wood against rot, fungi, moisture warp. and check. In 1929 arrived the light, allmetal alloy plane, which made possible tran-atlantic clippers and the 350 milean-hour pursuit ship. But the inside of each wing, each fuselage of an all-metal plane is a forest of carefully calculated stiffening frames and stringers; the outside is peppered with thousands of rivets It takes weeks, often months of the work of many skilled hands to complete such a plane. The great Douglas plant, under forced draught, needs 18 months to turn out 500 ships for the British.

NOW examine the "Clark 46," which in time may relegate metal planes to the shelves of history. Its fuselage is sleck, glass-smooth, and rivetless. There are a few discolorations and nicks on the belly, made by stones cast up from the wheels. (In the case of a metal fuselage, stones striking its underside leave notice. able dents) Otherwise its perfect flanks give no indication of the 1600 hours at has spent in the air, deliberately exposed to every flying stress and strain, to every onslaught of rain, sleet, and snow. Rap on it, and wonder at the light, unsubstantial sound. Peer into the dark interior, climb into the cockpit, and notice the complete absence of structural supports. All the space is free. And there is only a faint seam to show where the two 20foot half-shells that form the fuselage were joined together.

Colonel Clark has given the name "Duramold" to the new material from which this fuselage is made Manufactured by a secret process employing phenolic resus discovered by Dr. Backeland, Duramold, roughly speaking, is a laminated plastic similar to the glossy table tops and decorative panels often found in night clubs or cafeteria bars.

Technically, Duramold stands somewhere between the plywood built into airplanes between 1917 and 1931, and a true plastic. The difference between a

synthetic resin but virtually a new syn-Duramold does not chip or corrode; it resists water, oil, and acids; and is stronger than metal. Says Colonel Clark;

straight grain, are formed into the de-

sired curvature, that they are then fixed

into a mold, partially impregnated with a

phenolic resin, and then pressed into a

cohesive mass that is no longer wood nor

thesis.

"In the form of a simple thin-walled cylinder of given weight under compression, Duramold is, roughly, 10.4 times as strong as stainless steel, 3.4 times as strong as aluminum alloy, and 12.1 times as strong as reinforced solid phenol for-maldehyde resin (a plastic)." Its basic ingredients are cheap and, in part, absurdly common. Set in molds, Duramold can be given any desired shape-and will keep that shape.

The shape of a plane is all important. Experts in aerodynamics know that tiny bumps or depressions measurably interfere with the flight of a plane. In metal planes such flaws are hard to avoid; in planes of Duramold, true to a few tenthousandths of an inch, there need be none. Engineers have said that the "Clark 46" is, aerodynamically, the most nearly perfect plane they have ever flown.

And only the fuselage of the "Clark 46" is Duramold. The ailerons and rudder are of alloy; the wings are of im-

proved plywood—used partly because a plastic fuselage was sufficient for experimental purposes, and partly because Coinel Clark wanted to compare the behavior of the two materials. Even laymen who have examined the plane have remarked the fact that, while the Duramold has stood the texts of 20 months, the plywood has not. The wings, applied in sections—not molded in two longitudinal parts like the fuselage—show signs of repair. One joint has been damaged by the weather—or by rot.

Within a few months we shall see a plane in which wings as well as fuselage are made of Duramold, for the wings are no more difficult to fabricate. At the present stage of this new process, Duramold may be pressed in lengths no longer than 40 feet, giving a wing spread of 85 feet, ample for most military purposes. Duramold planes will be as strong as metal; more fatigue resisting, it is believed, as safe in the air; and probably less hazardous in a crash, since wood breaks more slowly than metal under impact Under gunfire, Duramold fuselages and wings will fare better than metal ones because they will have no vital structural points to be shot away.

BECAUSE of its seamless, rivetless skin, a high-speed, all-Duramold plane will have a frictional drag no greater than glass, and will be theoretic ally 7 percent faster than its all-metal counterpart. At 300 miles per hour, this would be a gain of 21 miles.

But the revolutionary feature of this new process is, of course, the speed of manufacture At the Haskelite plant in Crand Rapids, nine men molded a half section of the "Clark 46" in one hourtwo hours for the whole member. Shipped to the Fairchild factory, only 5 hours and 20 minutes were required to assemble the entire fuselage and fit it, without filing or drilling, to the completed plane. And this, remember, was an experimental job In factory production, when that comes, the time will be cut down even further. There is no reason why Duramold wings and fuselages may not eventually be turned out as rapidly as Fords.

Colonel Clark undertook his researches as a preparedness project. Having learned a lesson from our pitifully inadequate air building program during the last war, he foresaw a period of heartbreak for the air arm in the next war while production awaited the slow, manual job of fixing stringers in airplanes and fastening them with millions of rivets. The answer was the elimination of stiffeners and rivets. Sherman Fairchild, of the Fairchild Aviation Corporation at Hagerstown, shared his views; the chemists of the Bakelite Company advised; and the Haskelite Company, a laminated plastics firm at Grand Rapids, gave invaluable aid based on extensive experience which they have gained in the highly specialized field of plywood fabrication.

Personally, Colonic Clark in a wellgirthed, patient-wored gentleman of 53, with kind manners, an abstracted air, and blue eyes as cold as acadeuls. Born Unnontown, Pennsylvania, and christened Virginus Evans, Clark went to Annapolis, transferred later to the Army's Coast Artillery, fmally to the Aviation Section, Signal Corps. At 29, le was made chief

Col. V. E. Clark, veteran airplane designer, who is pioneering in the field of lammated plastics planes

nigneer of Army avatton, a post he held throughout the war and until he retired from the Army in 1920 to become chafceromatured engineer of General Motors at the Dayton-Wright plant. When General Motors withdrew from avatton in 1923, Colonel Clark helped organize and hecame chief engineer and vice president of Qmooldrated Arreraft at Buffalo, designing and huilding more than 800 training shaps there for the Army and Navy.

From the standpoint of national policy, the use of Duramold, or other easily obtainable plastics materials, would frequence on aluminum alloys. But what is more important, the Clark method may realize the long-standing dream of airliness as cheep and accessible as automobiles. It is not inconveivable that Clark might one day be the Ford of the sky-ways. The fact that production of plastics airplanes has no observable limits gives his enterprise exciting scope at this juncture in European affairs.

Nazi Germany terrified the world by turning out 10,000 metal planes in one year. The democracies—including ourselves—here that it would take months, perhaps years, to overcome this preponinstruments, propellers, fittings off the assembly line. But production logs down in the bottleneck of the great structural parts, with their thousands of man-hours and millions of rivers. The German war plane program calls for 160,000 skilled workers in the arrplane plants alone, plus 240,000 more to make parts and measurement sheeting, Duramold planes will break the bottleneck. With ten sets of dies, two hundred men in a factory covering one city block could build enough Duramold fixelage, wing, and tail shells for 300 planes a month; with 100 dies, 2000 workene, only semiskilled at that, could, in one year, mold and assemble 36,000 Duramold planes.

THESE things are just around the bend of the future. Colonel Clark. long a pioneer, has rivals Glenn Martin, who built hedgehoppers contemporaneously with the Wrights and Glenn Curtiss, has been conducting research in his Maryland plant for two years, and has established a fellowship at the Mellon Institute under Dr. William L. Rast, with the hope of evolving his own plastics type ship. Another group with a dozen chemists and engineers is at work at Hasbrouck Heights, N. J., under Eugene L. Vidal, former Director of Aeronautics in the Department of Commerce, They have already molded scaplane pontoons which are now being tested by the Navy. In Europe, the race for solution of the problem of mass production planes is furious, the contestants being England, France, Germany, Italy, Holland, and the U. S. S. R. The English De Havilland Company leads in research. Plastics propellers-lighter, stronger, and cheaper than metal-are being produced in England and in the United States. The German Heinkel Works is supposedly making three planes a day of plastics plywood panels-which is primitive compared with Colonel Clark's achievements. Another German firm is said by the British Aviation Journal, The Acroplane, to be installing 12,000-ton plastics molding presses, possibly large enough to form structural airplane parts. The implications of all this are tremendous When the new science of plastics has helped solve the problem of mass production of planes, the winged fear that made Munich possible need never be repeated No one nation will be able to cow another from the air for long, Portugal and Peru, if they wish, may have air fleets as large as those that terrorized Europe last September. Preponderance in aviation may give way to equality; planes may become as commonplace and unimportant in the balance of war and peace as rifles are today. The only possible superiority in the air may depend on morale, flying skill, strategy, and a ready supply of petroleum. If peace lasts until plastics planes are as much a reality as Fords, their sheer quantity may help to keep the peace. And to peacetime aviation, their cheapness, durability, and steadiness may open up as yet undreamed of vistas.

WHAT KEEPS THE STARS SHINING?

READERS who have had the patience to follow our story of stellar energy into a third installment may be excused for asking what dramatic conclusion justifies so long a tale. So far, we have built up the situation, and shown that the climax of the play must be a transformation scene, in which atoms of some kinds combine and change into atoms of others, with liberation of the energy which keeps the stars shining. This atomic-or, rather, nuclear-interplay was first fully interpreted, year recently, by the brilliant work of Professor Bethe of Cornell. The plot is a bit complicated, and it will be well if we begin with a list of dramatis personne-that is, of the various sorts of atoms, and of those of their properties which concern the action:

The Lighter Atoms.

Name	$S_{\lambda} mbol$	Charge	Wass
Electron	e	1	0.00055
Neutron	n	0	1 00893
Hydrogen	H1	1	1 00813
Deuterium	H^2	1	2 01473
Helium	He3	2	3 01699
Helium	He	2	4 00386
Lithium	Li ⁶	3	6 01686
Luthium	L_1 ⁷	3	7.01818
Bervllium	Bc	4	9.0150
Boron	B10	5	10 01631
Boron	B11	5	11 01292
Carbon	C12	6	12.00398
Carbon	C13	6	13 00761
Vitrogen	NII	7	14 00750
Nitrogen	N^{15}	7	15.00489
Oxygen	O ₁₆	8	16 00000

The masses given in the last column are the values for the whole atom-to get that of the nucleus, subtract the mass of the number of electrons given in the third column; for example, a hydrogen nucleus (proton) has the mass 1 00758, and a helium nucleus (alpha particle) 4.00276. The various isotones of the elements are listed separately. The more abundant ones are named in stalies. We have now to fix our attention on the small decimal parts of the numbers in this last column. In a reaction between nuclci-whether they combine or break up-the main part of the mass is not altered-only the small "mass excess" above a whole number. We may, if we will, think of the whole numbers as representing in some way the "quantity of matter" (whatever that may mean) and the decimal parts the differences in the

According to Bethe's Theory, the Most Notable Achievement of Theoretical Astrophysics of the Last Fifteen Years. It is Atomic Transformations

> By HENRY NORRIS RUSSELL, Ph.D. Chairman of the Department of Astronomy and Director of the Ob-servatory at Princeton University. Research Associate of the Mount Wilson Observatory of the Carnegie Institution of Washington

amounts of energy with which they are bound together into a unit. The tighter they are bound, the smaller, naturally, is the mass-excess.

It thus appears that the belium nucleus. and those of carbon and the following elements, represent configurations of low internal energy, while hydrogen is highest up on the scale (except for neutrons, which, as we pointed out last month, will be very short lived inside a star).

The transformation of hydrogen into heavier elements is therefore the main process to which we must look within the stars. Four neutral hydrogen atoms have a mass 4 03252, which exceeds that of a behum atom by 0.02866, or one part in 141. This looks small, but if the Sun was made of hydrogen, and turned into behum, the energy corresponding to the loss of mass would keep it shining at the present rate for 106 billion years. We have at last found an adequate source of stellar energy Other transformations would give much less, for example, to turn four helium atoms into one of oxygen (if possible) would diminish the mass by one part in 1040, and be but a tenth as effective.

WE may now-following Bethe-consider what is known about the various reactions between these atoms

In the first place, only hydrogen nuclei (protons or deuterons) produce effects of importance. An alpha-particle has twice the charge of the proton, and so is more strongly repelled, and, having four times the mass, it moves but half as fast at the same temperature. It is therefore enormously less likely to "penetrate" another nucleus.

Secondly, most of the nuclei in the table can be penetrated by a proton, if hit hard enough, and transformed; but there is one great exception. Helium is invulnerable. If a proton entered an alpha-particle and fused with it, the resulting nucleus would have mass 5 and charge 3-it would be Li3. It might be, however, that as the proton entered, it knocked out a positive electron, reducing the charge by a unit: this would give

He'. Neither of these has been found, experimentally; and there is very strong reason to believe that such nuclei are inherently unstable-not capable of independent existence for even the minute fraction of a second for which some radioactive nuclei endure. If two alpha-particles should penetrate one another, they would form Bes (charge 4, mass 8). This is now known to be unstable; it breaks up again into the two alpha-particles Hence belium, once formed, appears to be indestructible. Nothing more can happen to it. If hydrogen is the fuel of the stars, helium is the ashes,

Thirdly, the lighter nuclei, from deuterium to boron, react rather readily with protons. But, either at once or after two or three successive changes, the resulting products break up into helium. To take examples observed in the laboratory

Li +H1 = 2He4; B11+H1=3He4 If hydrogen and light elements are originally present, these reactions will liberate a large amount of energy; but each light nucleus, once caught, is used up, so that the process has a limit. With carbon, however, a new situation appears. As worked out by Bethe, the first reaction is $C^{12} + H^1 = N^{1,1} + \gamma$

that is, a proton enters the carbon nucleus, producing a new nucleus of mass 13 and charge 7 (nitrogen). The energy corresponding to the loss in mass is liberated as a gamma-ray (y). The nucleus N13 has been produced artificially, and is radio-active, emitting a positive electron, and dropping back to charge 6. $N^{13} = C^{13} + \epsilon^{+}$

Another proton builds this up into ordinary nitrogen C¹⁸+H¹=N¹⁴+γ

and still another into an isotope of oxygen

N14+H1=015+ This, again, is a known artificial radioactive element.

O15 = N15+e+ We might expect N15 to be built up into O16-common oxygen-but Bethe gives good reasons for supposing that, except in perhaps one case in ten thousand, the product of the next collision will break up into two pieces, according to the

For many heavier atoms, such as iron, there is a small "mass defect," but this does not con-cern us now

equation

 $N^{15}+H^{1}=C^{12}+He^{4}$

One of these is a helium nucleus—and the other is the carbon with which we started. We have here a regenerative process. The carbon is not used up, but reappears at the end of the cycle, and then et result is that four protons have disappeared, and been replaced by one alphaparticle. The energy corresponding to the loss of mass is illustrated in various ways—as gamma-ray, or as kinetic energy of motion of the ejected positive electron or alpha-particle, but these will quickly be converted into energy of heat-motion in the ray.

The positive electrons, by the way, will not last long. They will meet negative electrons, and, in this case (unlike whole atoms) the two may annihilate one another—liberating still more energy.

Finally, the rates at which all these reactions occur increase very rapidly with the temperature—but, at a given temperature—but, at a given temperature and density can be calculated in many cases from laboratory observations of the yield of the products under known conditions, and estimated in the others on the basis of a fairly extensive knowledge of the general properties of the nucleus.

Suppose now that we had a mass equal to the Sun's, containing (like the Sun) 35 percent of hydrogen, and all sorts of other elements. If it started with a very large diameter, its central temperature would be low, and none of the nuclear reactions would work. It would have to contract to keep shining, and so grow hotter inside.

WHEN the central temperature reached about 300,000 degrees (according to Bethe) hydrogen and deuterium would begin to interact, and by the time it had reached 400,000 degrees this reaction would supply enough heat to keep the star shining. The contraction would then almost cease until the deuterium was used up (not entirely, because, as it became exhausted, the temperature would have to rise a little to get enough heat out of the diminishing supply). When it was gone, contraction would ensue until, at about 2,000,000 degrees, lithium became available as "fuel called another halt, Beryllium would work at about 3,000,000 degrees, and the two isotopes of boron at five and nine. With all these possibilities, the star might keep going for a good while; but so far as we can determine from the study of the spectra of the Sun and the stars, all these light elements are rare; their total amount is but a very small fraction of the hydrogen.

When they were all gone, there would be more contraction till, at a temperature of 15,000,000 degrees, carbon began to be attacked. At first the carbon would be turned into nitrogen: but, at 18,000,000 degrees, this too would react. Bethe's cyclical process would then be in operation—the carbon would be regenerated, and act as a catalyst to turn more hydrogen into helium. This stage would continue so long as any hydrogen was left—that is, for very much longer than all the previous offers.

We should therefore expect to find the great majority of the stars in this situation—but how can we check this by observation? The test is very simple—the central temperature, calculated thus from

Hans Albrecht Bethe, professor of physics at Cornell University and originator of the notable theory

atomic theory, should agree with that derived from observations of the stars.

The rate of the carbon-chain reaction increases very rapidly with the temperature—about as its 18th power. Hence, in a star which radated 100 times as much heat per unit of mass as the Sun does, the temperature would have to be only 14 percent higher (if the density work the same too). That is, most of the stars should have central temperatures of about 20 million degrees.

Now it has long been recognized that the stars of the man sequence—the most important of all groups—have all about the same internal temperature, and, when allowance is made for the hydrogen present, the temperature comes out close to 20,000,000 degrees. Even the differences between the bright white stars at the top of the sequence and the smaller and cooler ones like the Sun are represented by the theory. Bethe gives the following comparison (central temperatures in millions of degrees):

Strius U Ophia Y Cyrni 18.5 22 26 30 Theory 32 Observation 19 26 The theoretical values would be changed by a few percent by different assumptions as to the amounts of carbon and nitrogen present in the stars, and the observed values by different adopted "models" of internal density. But the conspicuous agreement could hardly be vitiated.

Here we reach the climax of the drama. Previously we could calculate, from the general properties of atoms, that a star of given mass and hydrogen content should be of a certain brightness. Now, from the properties of atomic nuclei, we mass should also be of a certain dameter, and a corresponding surface temperature.

In other words, from the mere atatement that there is a body having 330,000 times the Earth's mass, and containing 35 percent of hydrogen, we can predict that it will have the size, brightness and temperature of the Sun. We could do the same for Sirus, and for innumerable other stars. The Main Sequence is theoretically explained

This is the most notable achievement of theoretical astrophysics since the establishment of the relation between mass and luminosity, and deserves all the credit that can be given it.

Certain consequences of Bethe's theory may be briefly discussed in closing.

Nuclear reactions involving heavier atoms-for example, building up oxygen into fluorine-are quite possible, but they would work at an appreciable rate only at higher temperatures than the carbon cycle, and so would not have a chance to happen in the stars Bethe and Gamow have given a great deal of attention to the question whether side-reactions, which happen to only a small percentage of the nuclei in a star, may build up heavier atoms, but have found every road blocked. There is at present no explanation how such elements as sodium. calcium and iron can have been formed. We must assume that they are "older than the stars" and for the present let it go at that.

THE history of a star, after the carbon to cycle is at work, appears to be fairly clear. As it gradually uses up its hydrogen, at must get nighter—and expand a little, to keep its central temperature from rising too rapidly. After a very long time (Bethe calculates 12 billion years of the thing of the Sun ji the hydrogen will become exhausted, the star will once more contact and draw upon gravity. Stars of small mass will end up as white dwarfs; those of large mass will shrink still more.

Finally, the giant stars are not yet accounted for. Their central temperatures must be far too low to "turn on" the earmon experiments and their stars of the star too low to "turn on" the earnally upon a very different model with very high central condensation. This may be true: or they may contain large quantities of light atoms, and be consuming these; or perhaps they draw upon some energy-liberating process whuch has not yet been duplicated in the laboratory. We must at the moment rest uncertain—and the students of the stars have still something to work out.—Princeton University Observatory, April 5, 1939.

Rubber's 'Little Brother'

AMERICANS have become so accustomed to newspaper headlines proclaiming another minor miracle in science that it requires an outstanding achievement nowadays to make them pause and take notice.

Such an achievement has come out of the laboratory of the oldest rubber company in the indidle west where scientists have brought into the world a synthetic material so closely akin to rubber that it is being called rubber's little brother. The new substance is Korseal, and, siginficantly, its wonders can be introduced to the world on the one-hundredth anniversary of the discovery. In Charles Goodyear over his Mas-achiesetts kitchen store, of the process for vulcanzing rub-

Koroseal is not a synthetic rubber its scientific god-parents are careful to point out, for no true synthetic rubber exists

Purified basic ingredients of the new material. Limestone, coke and salt are so common that only factors conditions can limit production

in the world today, although there are other rubber substitutes. Scentists have been searching for decades for the secret of nature that would enable them to manufacture rubber cheaply in the test tube, but the quest has been catalogued with such "impossibles" as the photospher's stone "Vet Korosad, Ist do doverers confide, has many of the qualities a synthetic rubber's should possess and is, in fact, better in some respects than natural rubber II is made from such comnon substances as limestone, coke, and salt.

This new chemical compound opens up a vist new field of utility because it has proved its ability to operate in places where rubber never could perform It is adaptable to varied uses, and in a variety of forms ranging from the fire-resisting coating on power transmission cables to lining in hot acid tanks and the fine-

textured clothing in milady's wardrobe Since natural rubber is an indispensable product in daily life, and, therefore, a vital commodity in war-time, the discovery of Koroseal is highly significant as nations rush ahead with armaments. In the United States, a number of rubber-like synthetics have been developed since the World War, but the total annual commercial consumption of the artificial products has amounted to only about 1 percent of that of rubber. Nevertheless, such scientific strides have been made with these synthetics that the price of one artificial rubber product has been lowered from \$1.05 to 65 cents a pound. while natural rubber hovers currently about the 15-cent mark

Some American chemists have been bold enough to predict, in the light of rapid developments in the synthetic rubber field, that the rubber industry could make the United States independent of the need for natural rubber in one year with a sizable expenditure for equipment to manufacture Korosqal and other syn-

This elaborate gown, prize-winner at America's first Rubber Ball, was fashioned of Koroscal.

thetic, rubber-like products. They point out that it required much larger sums and many years longer to bring natural rubber to a point of wide utility.

Significantly, scientists point out that it would require an acre of rubber trees 17.520,000 hours, or 2000 years, to produce the same amount of natural rubber which could be turned out synthetically in one hour by a laboratory only one acre in area. This fact alone dramatically illustrates the importance of any synthetic material which possesses qualities that would enable science and industry to substitute it in services where natural rubber long has functioned For in commercial use today, rubber is the vital sinew of more than 32,000 varied products, most of which are indispensable to every-day life.

MANY "first cousins" of rubber have bobbed up in the laboratory, but only in very recent years have products been discovered and developed which, in addition to having rubber-like physical

properties, are so chemically constituted that in many special cases they will outserve rubber. For example, acids that chew the life out of every metal except the "noble metals," and devour stone or glass with equal case, leave Koroseal unblemished. Oils that permeate the pores of many substances, including rubber, and cause them to swell, soften, and disintegrate, practice their wiles in vain on Koroseal. Oxygen, great leveller of flesh, wood, and iron, won't leave a smudge on its face: and in resistance to water, a duck's back is no better. by comparison.

Koroseal's sire is a corrosive gas and its dam a colorless flammable gas. The factor which gives Koroseal and edge over rubber is its immunity to ozone, rays of the sun, and oil—all deadly enemies of natural rubber. Howmies of natural rubber. OF the mis-called "synthetic rubbers" commercially available today, only one is dealt with speciheally in the accompanying artub-There are, in fact, three important synthetics in this class; the following paragraphs summarze their characteristics and detail the useto which industy is putting them

Koroseal products are resistant to moisture oxygen, ozone, strong aids and alkalies, and most corosive chemicals. Typical applications are wire and cable insulation and sheathing, textile roll covering than lining, pipe covering, outling for plating racks, chemically-resistant tubing, impregnated fabries.

Neoprene is used primarily because of its resistance (1) to swelling in oil and gasoline. (2) to

cracking in sunlight, (3) to deterination under coddizing conditions, and (4) to softening at fairly high temperatures. It finds application in curb pump gasoline hose, crade oil hose, distillate hose, automotive goods such as gas-ket and vibration insulators, puring plates and oilers, oil resisting tiansmission and conveyor belts, oil resisting packing, and

Thiokof product are noted to their resistance to solvents, larguers, gasoline, and oils; their resistance to sunlight and ozone; and then low permeability to gases. Principal uses are lacquer hose, crude oil hose, cutcut-b pump gasoline hose, ignition code, impregnated paper gaskets, and printing plates. The Education

ever, scientists still face sev eral problems in connection with Koroseal. There is, for example, the problem of resiliency where Koroseal lacks characteristics of rubber Then, too, while Koroseal can adapt uself to temperature ranges from minus 40 degrees, Fabrenheit, to plus 150, Fabrenheit, research experts hope to increase this range and to change some of its present characteristics so that it will maintain a more stable consistency under temperature changes.

The peculiar difficulty of kotoweal to react favorably under wide variances of temperature makes it unadaptiable, at present, to automobile tries, Likewise, it cannot function under conditions where abrasion is encountered at high temperatures, although at low temperatures Koroseal can withstand abrasion very

well. With the objective of effecting these improvements, a staff of 20 technical expects is at work in the laboratory of TB. F. Goodrich Company, where the synthetic was discovered, to overcome its disadvantages.

Koroseal made its first commercial appearance quite insuspiciously to rid electro-plating of one of its greatest handcaps since that industry's inception. Some metal racks on which were suspended objects to be plated in elevation which were found to absorb more metal than the products plated. Some acel a peculiar resistance to plating solutions made it highly satisfactory for insulting these reasks. It has found its way into the steel industry as a lining for pickling wats, and it is the only material so far dissovered that defes the bot atalow which are used in the spickling that is a similar to the spickling wats, and it is the only material so far dissovered that defes the bot atalow.

The new material so nearly resembles rubber that it may be worked on rubber machinery

steel. Recently, petroleum engineers in the west discovered that the great underground network of pipes which transports oil many miles from field to reservoir was being destroyed by salts of the earth acting upon the metal. Koroseal came to the rescue, supplying a praterive coating smillar to the pickling vat lining.

Transparent Koroseal is superior to any other flexible material in reasting the diffusion of certain toxic gases which might be used in wartine. The psychological effect of a transparent Koroseal gas mask is said by scientists to lift the soldier's morale 100 percent. Another possible war use for Koroseal is its application to soldier's uniforms, by coating or impregnation, to prevent mustard gas wounds. During the World War, thousands of soldiers received life-time wounds from this vicious gas, one of the most difficult to combat on the battlefield. Koroseal is three times more effective than rubber in resisting mustard gas.

It is evident that this new synthetic has boundless possibilities in the field-of transportation, communication, and heavy industry, as well as in countless varieties of products, including wearing apparel. It can be poured, molded, or cut, coated, painted, impregnated, or laminated. It can be firmly attached to metal, fabric, or even to natural rubber.

BECAUSE Koroscal can be made jelly-soft or hone-hard, it has an extreme range of utility. The soft form, Korogel, was one of the first products sold com mercially, it was found highly satisfactory for making flexible molds from which plaster reproductions of art objects could be turned out with great facil ity, Koroseal's indifference to oil has made it possible to create molded partfor hydraulic shock absorbers and for gaskets, cups, or plungers which must withstand oil or grease The laboratory has practically completed the develop ment of a form of Koroscal for use as a container material for liquids, such as acids and oils, which cannot otherwise be marketed without considerable pack aging expense.

Since it is waterpriod, sun-resisting and heat-repelling, foro-seal is especially adaptable to the home for table coverings, will paper, draperies, shower curtains, covering for outdoor furniture, and a horde of other uses. It can be utilized as a transparent coating or readily takes colors ranging from the brightest hines to the mistest pastels. Brightly colored printed lines, silks, and other fabrics, impregnated with Koroseal, are being turned into attractive rangy day garments.

Relativity 20 Years

(Part Two) The General Theory

TURNING to the general theory of relativity, whose most distinguishing feature is its theory of gravitation, we find a very different situation from the one described last month with regard to the special theory, While gen erally acclaimed as one of the most important achievements of modern thought, its restricted field of application has severed it from contact with the most vital advances of present-day physics. Although both theories have been the target of hosts of irresponsible fanatics, the aloofness of the general theory has made possible attacks on it by a few presumably responsible scientists-even though it has, by and large, received

general acceptance because of of the few observational effects which it predicts, and general admiration as a monumeral accomplishment of the human mind, In evaluating it we must be careful to seek the open May between the Scylla of blance and the Charyddis of neglect engendered by the myope view of the more extreme pragmatic cults.

In developing the general relativity theory of gravitation, Finstein took his cue from the empirical fact that the mass of a body, which is a measure of its ability to resist change of motion, is at the same time a measure of its ability to attract other bodies. This equivalence of "inertial" and "gravitational" mass is now attributed to the fact that in the general theory they are but two different aspects of one and the same thing-which we may, with suitable caution, take as a measure of the "curvature" of the physical space-time continuum. This geometrization supplants the Newtonian law of

gravitation, to which it is equivalent in the first approximation, but its astronomical predictions differ from the classical ones in certain extremely minute details, the principal ones being the advance of the perihelion of Mercury, the bending of light passing the Sun, and the shift toward the red of light from massive bodies. In spite of the relative mignificance of these effects in the loader scheme of things, and in part An Evaluation of the Achievements of the Special and General Theories of Relativity During the 20 Years which Have Elapsed since the First Direct Observational Test of the General Theory

By H. P. ROBERTSON, Ph.D.

because of the difficulties encountered in verifying them, there has been an unfortunate tendency to magnify their importance as crucial experiments, ignoring the more fundamental and most accorately verified cornerstone of the theory the above-mentioned identity of gravitational and merital mass.

Professor Einstein seated in his comfortable old reading chair in the study of his modest, old-fashioned home,
smoking one of his pet pipes as he reads. Three walls of
the study are lined from floor to ceiling with books and
periodicals. The fourth is a large plate glass window

Even so, these three astronomical consequences have given a good account of themselves since their enunciation two decades ago, and in each case have lent weight to the theory, for even in those observations which fail to reveal decisively the predicted effects, the results are less discrepant with relativity than with classical theory. The question of the advance of Mercury's perihelion can now be answered in the affirmative more

firmly than at the beginning of this perrod; its severest critics have never been able to establish their case against it, and the improved orbit announced by K. P. Williams of Indiana last year is completely consistent with the predicted advance. The bending of light from stars at the limb of the Sun, perhaps techniquely the most difficult of versions.

ification, seemed for a time reasonably established from the plates obtained during the 1919 and 1922 eclipses, which yield an average deviation but 2 percent greater than the value 1".75 predicted by the theory for a star seen just past the limb of the Sun. But Freundlich and collaborators in Potsdam. on working up plates obtained during the 1929 eclipse, were led to a deviation of 2".25 and, although an independent reduction made by Trumpler of Califorma led to the predicted value, the original authors attributed this to arbitrariness in the reduction of the observations. In any case, the evidence is clearly in favor of the Einstein effect as opposed to the smaller value of 0".87 expected on the Newtonian theory; future eclipse plates may be expected to yield a more definitive quantitative check on the theory.

The third test, the shift of spectral lines toward the red in

light from massive bodies, is so small in the case of the Sun—a shift of the order of one one-hundredth of an Angstrom—that its existence is most difficult to establish, St. John of Mt. William announced tentatively in 1923 that the residuals, after allowing for known effects such as the Doppler shift, were more consistent with the relativistic than with the classical theory; such is also the conclusion of the recent excellent work of the English astronomer Ever-

AFTER

shed on the problem. An unexpected test of this effect was furnished by Adams of Mt. Wilson in 1925, when he found that the companion of Sirius, a white dwarf, showed a residual red-shift 30 times as great as that expected from the Sun. Now the mass of the star is known, from the orbit, to be about 85 percent of that of the Sun, and the theory of these stars indicates that its radius should be between 21/2 percent and 3 percent of the Sun's radius; the shift predicted by the theory for such a star is, to within the errors attendant upon such work, just that observed. This may be considered a most valuable indirect confirmation of the theory of relativity-or of the theory of dwarf stars, whichever is considered the more doubtful! It is often remarked that this effect is also a consequence of the photon theory of light, the shift being due to loss of energy by the light-quant in escaping from the gravitational field, this derivation is, however, dependent on the general theory of relativity, as it assumes the identity of inertial and gravitational mass for light.

WE turn now to the cosmological problem, and the speculative attempts to answer questions concerning the geometry and physics of the space time universe as a whole The general theory of relativity attributes local irregularities in the geometry—that is, local gravitational fields—to irregularities in the distribution of matter; thus the 4dimensional geometry of the neighborhood of the Sun is such as to cause a planet to pursue what we, with our traditional ways of thinking, would express as a curved orbit described under the action of the Sun's gravitational field. This raises the question of what the geometry of the observable universe might be if we were to ignore these irregularities due to the agglomeration of matter into stars or systems of stars-that is, what the worldgeometry would be if all matter were considered as more or less uniformly distributed in space. The first attempt to answer this question is that given by Einstein in 1918; on assuming that the mean density of all matter in the universe is a constant throughout space and for all time, he arrived at the view that space is closed-the 3-dimensional analogue of the 2-dimensional surface of a sphereand that, accordingly, the total amount of matter in the universe is finite. The curvature of space, which is measured by the inverse square of its radius, would depend, and in a sense be due to, the

total amount of the matter contained in the world. In order to obtain this solution. representing the world as on the whole static-the distance between any two nebulae remaining constant except for fluctuations which would iron out in the long run-it was necessary to introduce more or less arbitrarily a certain constant. The introduction of this "cosmological constant" λ is a freedom allowed by the form of the fundamental equations of the theory of gravitation, but one which is unfortunately subject to no direct observational check. Although on the hypothesis of the "Emstein universe" à can be indirectly determined from the total amount of matter, this is an interpretation which is not valid in the more general solutions of the problem which are to be considered below

The great Dutch astronomer de Sitter seized upon the possibility opened by the introduction of λ to consider a universe in which the curva-

ture is due entirely to the unknown constant, and in which the total amount of matter is so small as to have but a negligible effect on the curvature But, in attempting to apply these hypothetical models to the explanation of large-scale phenomena in the actual world, both met with little success. In the first place, a most surprising effect was slowly coming to light through observations on the spiral nebulae, those great systems of stars, analogous to our own Milky Way system, distributed more or less at random throughout the observable universe. For they were found, almost without exception, to be receding from our galaxy or, at least, their spectra exhibited a shift toward the red of exactly the same kind as that which would be caused by a motion of recession along the line of sight. And further, the more faint the nebula, and therefore presumably the more distant, the greater was the velocity of recession. This was a phenomenon utterly inexplicable in terms of the Einstein universe, and although it could be accounted for in terms of the de Sitter model the amount of matter contained in the nebulae was found to be far too great to be considered as having a negligible effect on the geometrical structure of the universe.

Under these circumstances it seemed most natural to seek an intermediate solution, which could explain the existence and nature of this recession, but in which the effect of the matter was adequately taken into account. A family of possible solutions—actually, as it turned out later, the most general—was found by the late

Prof R. C. Tolman, physical chemist, mathematical physicist and dean of the Graduate School at the California Institute of Technology, one of whose special interests in the world of science is relativistic compolery.

Russian mathematician A. Friedmann, in 1922, and has since been the subject of exhaustive investigations by Lemaître of Louvain, Tolman of Pasadena, the present author, and a host of others, Among the multitude of special cases contained in this most general solution were some in which A was positive and space finite (at present the most favored), others in which A could be set equal to zero and space taken either as finite or Euclidean, and still others (including all those for which \(\lambda\) is negative) in which the "radius" of the universe oscillates between a fixed maximum value and a very small minimum. The principal problem was then the determination of just which of these models would best fit the actual observations-that is, which choice of A and the curvature would give a model which best reproduced the large-scale phenomena of the actual observable uni-VATSO.

THE observations which were available for this selection, asy in 1933,
yielded two of the required empirical
date—the red-shift constant and an estimate of the density of smoothed-out matter. The former was obtained from the
work of Hubble and Humason of Mt.
Wilson, according to which the red-shift
of nebulae increases 550 kilometers per
second with every million parsecs of distance, and the second was obtained from
the Hubble's estimates of the mass of an average nebula and the mean distance between them. But unfortunately these two
important results were not enough, for

unique solution—which accounts for the great variety of models consistent with which we were bombard ed at about this time. But all these solutions had one surprising feature in common, they all indicated that the presentations of cold have gone on for at most a very few thousand million years, not much more than the age of the Earth as defined to the solution of the solution of

The Canon Georges Lemaitre, of the University of Louvain, one of the first to study the red shift

of the oldest geological strata? Although such a limited time would be difficult to reconcile with most of the theories of stellar evolution, there were nevertheless other observations which seemed also to indicate a comparable age for the solar system and the galaxy, many astronomers accordingly reconciled themselves tentatively to this. Short time scale."

More recently another survey, again by Hubble, promised to supply the data needed to narrow down the selection of possible models. This consisted in counts of the number of nebulae in selected regions whose apparent magnitudes were less than certain limiting magnitudes, five such counts, ranging from magnitudes 185 to 21.0, were obtained These may be thought of as giving the number of nebulae within a certain limiting distance of the observer. A little reflection on the nature of the surface of a sphere will make it clear that, in the three-dimensional analogue under consideration, the law of increase of these numbers should theoretically depend on the curvature of space; if their dependence is sufficiently marked, it should be practicable to obtain the curvature from these observations. Now the rate of increase of nebulae with distance, from these data, is different from that in a Euclidean space, the discrepancies being so large that if they are due to the proposed effect, the curvature must be surprisingly large. In fact, so large that the only model which fits both it and the red shift data has a most uncomfortably small "radius" (470.-000,000 light-years) and a still more limsted time scale-less than a 1,000,000,000 years, no compelling way of reconciling this latter with the geological time scale has yet been suggested. But this is not the only trouble, for the mean density of matter in such a model exceeds that contuned as luminous matter in the nebulae by a thousand-fold and, although it is conceivable that the universe contains this much dark matter, we have as yet no independent justification for assum my that it does.

TWO alternatives for escaping from Two alternatives for escaping at hand. First, the assumption of uniform density may not be a sufficiently valid approximation for the nebular counts, as relatively small fluctuations in the density of nebulae in the survey regions would be sufficient to account for the discrepancy without the introduction of such a marked curvative effect, this possibility has been suggested by Shapley of Harvard, who has recently published data in support of it from a survey of nebulae in the southern hemisphere Decision on this question must presumably await further data -we may hope that it can be decided one way or the other with the aid of the 200 inch reflector now under construction at the California Institute of Technology The other possible way out is to seck some effect hitherto unnoticed —perhaps to assume that the red-shift is due to a degradation of energy in light traveling great distances, and not to the effects of motion away from us. Although many such ad hoc explanations have been offered, it is contrary to respectable scientific methodology to accept any of them until they are supported by some independent verification

The search for a unified field theory. which will geometrize electromagnetism in a way analogous to that in which the general theory treats gravitation, has not been successful. The most promising of these was that of Weyl, at that time in Zurich, but it too had to be surrendered: his fundamental principle of "gauge-invariance" has, however, been incorporated into modern quantum theory, where it promises to be an important tool for a future quantum electrodynamics. It has been found possible to give a mathematically unified treatment of electricity and gravitation by the use of a fifth dimension. as in the theories of Kaluza of Gottingen, Klein of Stockholm, and Veblen and Einstein of the Institute for Advanced Study. but this has not in itself materially furthered the physical problem. No attempt has been made to review here the status of Milne's weard cosmological theory, nor of Eddington's unholy union of quantum and relativity theories; these theories have been attacked as representing a return to the outmoded Aristotelian method in semence—the attempt to derive natural law from a pitori principles. It would therefore seem that, although at least the latter claims to have solved many of the really outstanding problems of physics, the acceptance of the methods by which the solutions have been obtained would interest in a backward step.

In conclusion, the past 20 years have seen the special theory of relativity more and more firmly established as one of the most important and useful fields of modern physics, without which much of the modern work on atomic and nuclear structure would have been materially curtailed, if not impossible. On the other hand, the general theory has had but little contact with the advancing front of physical science, its theory of gravitation has been successful in the limited range of astronomical phenomena in which it differs from the Newtonian, but its most important achievement has been the estabh-hment of the identity of mertial and gravitational mass an achievement which may be expected to grow in im-

Dr Edwin P. Hubble, Mount Wilson astronomer, who has contributed invaluable data on the red shift

portance with the advent of some adcunate theory of the ultimate constituents of matter, even though it may at the same time suffer radical modification. The rise or fall of its cosmological offshoot, the theory of the expanding universe, can be expected to have but little effect on the general theory; as long as the theory of gravitation is accepted, any attempt to approximate the real world in terms of a homogeneous background must utilize one of the models with which relativistic cosmology is concerned-even though it would constitute an awkward anticlimax if it turned out that the red-shift were due to some agency at present unknown rather than to the expansion, to which these models seem so admirably adapted!

LOOKING FOR TROUBLE

Chromium plated gadgets and super-streamlising will sell an automobile. But to keep it odd sultons complaints is the reason why manufacturers maintain elaborate inspection companion. It is cannot be examined, at the right is shown one of the tests employed by one motorar maker. Steering knuckles are being magnetized prior to inspection for forging flaws. Any minute flaw behaves like a magnet and is discovered when the knuckle is depiced into a supersist of its order.

The illustration at the right shows an electrical thickness gage which is being used to "raliper" the engine walls It contains coils which create a magnetic field in the walls. The gage above measures the field strength; the safe has graduations that indicate exhibited wall thickness in 64th s of an inch

One of the most accumite and exacting jobs is that of futing justing just to pust on. This is a function of the inspection department. The illustration at the left shows a badraulic future for inserting just. The gase militarists the pressure required to torce the jun into place. Tolerance limits are marked on the duly partial respected if too much to too luttle pressure is used.

Not only is the inspection department responsible for the materials and ports which so into the automobile; it must check all master parts. At the left is showed one of the most check all master parts at the left is showed one of the most it is being used to check the cautout of all surfaces of one of the master cans that are used to control one manufacture, or a canshaft production. Also, it is used in starting the production of a new model, for by means of this instrument is too he determined evartly what part of any surface is insecurate. The mirrometer scales are graduated to 0.00005 of an inch

THE GREAT AMERICAN RITE

WRITING in Muneaton Medicine Medicine Medicine Medicine Medicine ally used this tutle: "The America ally used this tutle: "The America and Medicine Medicine

Broadly speaking, said this physician, tonsils should be removed if they are greatly enlarged and amount to throat obstruction, if they are the seat of pronged inflammatory disease; also if they can be proved to service poisons—which brings up the theory of focal infection. Many children lose perfectly good tonsils which have swellen only temporarily while waging defensive warfare against infection, a congestion that can recur without permanent enlargement. The tonsils of infants should seldom or never be removed—that's what the Minnesota doctor and, take to r leave it.

The British journal, The Medical Officer, has also commented on the recent fashion of tonsil removal In October. 1932, it remarked that a mere temporarily enlarged tonsil did not merit removal. and that it was impossible to divide tonsils into septic and nonseptic Indeed, it said, we really have no way of settling whether they should or should not be taken out. In October, 1938, it was even more emphatic, A Dr J. Alison Glover had just presented to the Royal Society of Medicine "strange facts" to speak for themselves. From 1929 to 1931 almost four percent of the children in Derbyshire had had their tonsils removed, but in 1933 the number had dropped to one tenth-vet there was no deterioration in child health. In two neighboring districts in London the respective removal rates were four percent and two tenths of one percent, without discernible differences in the health records of the children.

True, the idea that tonsils should go is an old one Hundu physicians have removed them for ager—at least as early as 1000 p.c., but the theory of "focal infection," as it is known today, stemmed from articles by Dr. Frank Billings published between 1912 and 1914. In them, Billings as-cribed arthritis, nephritis, and later a wide variety of ailments to infected teeth in his Lane Memorial Lecture in 1915, Dr. Billings defined a focus of infection as a circumscribed area of infection and the contraction and the contraction area.

What Many Doctors Think About the Too Casual and Routine Removal of Tonsils . . . The Public is Partly to Blame . . . Are Tonsils Useful?

By T. SWANN HARDING

not nearby at all. As such foci of infection, he cited particularly tonsil abscess es, chronic sinus infection, gallbladder and appendix infections, and bad teeth E. C. Rosenow and others further developed his theory mainly by work on animals

In 1938, Dr. David Riesman began to speculate as to whether painless, decayed teeth also might not cause ailments elsewhere in the body. Nor is there anything wrong with this theory, within strict scientific limitations. When it can be proved that a focus of infection definitely is causing disease elsewhere in the body. the focus-tonsil, teeth, gallbladder, appendix-should be removed. Often, however, the removal takes place in the absence of good evidence to indicate that the result will be good. And so many "preventive" removals do not act preventively. Too often the operation has not good, but bad, after-effects.

CONSIDER bad teeth. In The Journal of the American Medical Association as long ago as October, 1919, you will find an article by Dr. Walter C Alwarez entitled "A Protest Against Reckless Extraction of Teeth" which is as true today as it was then. Too often removal of the teeth or of any other supposed focus of infection has no beneficial effect upon the patient's health. "In view of the fact that the most thorough removal of focal infections often falls to cure arthritis and other diseases, let us be more honest and other diseases, let us be more honest and other diseases, let us be more honest and conservative with our patients," wroce Dr.

Alvarez In the same journal, in May, 1923, the same doctor wrote on "Lessons to Be Learned from the Results of Tonsillectomies in Adult Life." He demonstrated. after following up more than 300 cases, that the resultant improvement in health supposed to follow the tonsil amputation often did not occur. Those who had tonsillitis were almost always helped, but those who had no sore throat or tonsillitis were rarely pleased with the result of their operation. It paid best to remove tonsils for tonsillitis or sore throat. It paid less well to remove them for frequent colds. It did not pay at all to remove them on general punciples, as a preventive measure in the hope of helping headaches, deafness, enlarged neck glands, rheumatism, halitosis, and so on. In many such cases health became definitely worse after that operation than before. In two thirds of the rheumatism cases there was no benefit.

In many cases, Dr. Alvarez continued, repeated operations had been undergone because certain physicians attributed symptoms to tonsil fragments left behind by others. Some had had three and four operations with no benefit. Many had had tonsils removed for most trivial reasons. Another man decided to have his tonsils out because of one mild attack of constipation. He nearly died of pneumonia following the operation. Two others succumbed to the temptation because they had physicians as personal friends who would operate gratis. Another had his removed because he blinked his eyes; he still blinked after his tonsils were subtracted. Another thought the operation would cure his insomnia. As a whole, nearly one in ten victims of tonsillectomy had bad results.

Some nearly bled to death in the opcration or died of pneumonia afterward Some had recurrent bronchitis, difficulty in swallowing, odd feelings in the throat, loss in weight, nervous breakdowns, increased frequency of colds, sinustis, ear noises, or no relief from the original symptoms leading to the operation.

It should be emphasized that, according to an editorial in our leading medical pournal in 1926, both tonsil operations and mass extractions of teeth ought to be classified as major operations. Broncho-pneumonia and lung abscesses can and often do follow tonsillectonies under ether. Very severe and sometimes fatal complications have also followed an occasional tooth extraction. Tonsillectony under a local anesthetic is relatively safe. In other words, these are operations that should be undertaken only when the indications clearly justify such drastic procedure.

In short, the entire literature on tonsillectomy is convincingly consistent in showing that too many tonsils are sacrificed and the expected beneficial results too rarely occur.

Go back to 1927. In The Journal of the American Medical Association for December 24, you will find Dr. Albert J. Welch giving a statistical report on 1000 pairs of tonsils excised. In nearly half the cases no benefit to health resulted. Bacterial studies were futile because any organism having access to the mouth-and that means myriads—can be shown to be present in the tonsils. Only four bad infective or malignant lesions were found in the lot. Only 70 showed ulceration.

In 1928, a Public Health Bulletin, No. 175, appeared and the work of Dr. Kaiser of Rochester was also being discussed. Kaiser found that tonsil removals did nothing to remedy rheumatism, chorea, or heart defects in children but did reduce sore throats and head colds. The Public Health Service bulletin indicated that tonsillectomy did not reduce the frequency of sore throat among children. But it added that the words "normal, "discased," and "enlarged," as applied to tonsils, were meaningless because so differently interpreted by different peo-

N the December, 1928, American Heart Journal you will find a report on 413 tonsillectomies which had no effect on rheumatic infection. Neither were they beneficial in heart disease.

In the Archives of Internal Medicine for April, 1931, Dr. Ruby L. Cunning-ham discussed "Normal, Absent, and Pathologic Tonsils in Young Women," making a most careful study of the entire literature on this subject. She showed that all sorts of unproved hypotheses were held on the basis of poorly controlled and interpreted clinical observations. Careful statistical studies were made of 12,530 white female students, one third each with normal, absent, or diseased tonsils. The incidence of measles, mumps, chickenpox, whooping cough, scarlet fever, diphtheria, pneumonia, pleurisy, chronic colds, chorea, appendicitis operations, mastoiditis, and nasal operations was the same among the normals as among those with diseased tonsils. The group with absent tonsils actually had a higher incidence of all illnesses and operations than did either the normal or pathologic groups. Indications were that the removal of tonsile had had little helpful effect,

"A review of the literature relative to the effect of the condition of the tonsils on general health reveals a great lack of accurate information on the effect of tonsillectomy, when one considers the number of operations that have been per-formed," said Dr. Cunningham. Opinions were widely variant. But, even at that time, there was a sharply growing sentiment against taking the tonsils out for preventive or prophylactic reasons.

The trend of these investigations shows

an unvarying consistency. We shall note but two more of them. Glover and Wilson reported in The British Medical Journal in September, 1932, on the end results of removing tonsils and adenoids from adolescents and, in general, found that they did not justify the great number of such operations. The incidence of sore throat might thus be slightly diminished, but colds were just as frequent, otitis, mastoid disease, bronchitis, and pneumonia also. No one could claim that

A doctor must be a hero to fight off some who shop for operations

the operation helped in acute rheumatic or heart ailments. The conclusions of Dr. Cunningham (above) were considcred fully supported and "a large proportion of the tonsillectomies now done in children are unnecessary, entail some risk, and give little or no return.'

Finally, in The American Journal of the Diseases of Children, for August 1932, will be found reports showing that the removal of the tonsils affects neither susceptibility to diphtheria nor the incidence of scarlet fever. Meanwhile there is always a possibility that the tonsils actually perform some useful function, as Dr. Ivor Griffiths of London suggested in The Lancet for September 25, 1937. In some cases, said Dr. Griffiths, treatment of the sinuses would give the relief expected from tonsil removal. Removal of tonsils does not improve cases of middle ear disease, nasal catarrh, or acute explosive snoring. He then propounded the theory that the function of the tonsils was to excrete into the pharynx certain organisms that pass into them from the sinuses via the lymphatic glands. Hence tonsils should never be removed for nasal catarrh, Various experiments on dogs were offered in evidence. Dyes did pass into the tonsils via the lymphatics. Moreover, Dr. Griffitha did not think the helpful results commonly attributed to tonsillectomy usually occurred as hopefully predicted. He found discharging ears and mastoid dis-ease in many of 5000 tonsil-less children. He held that many objectionable living

bacteria are routed to the tonsils to be excreted into the alimentary tract for destruction. Hence it appears probable that tonsils are of some use. They may not only perform regular lymphatic functions, but they have this special bacteria-destroying function also (such is this theory) because of their anatomical position, And, advertising to the contrary notwithstanding, it should be emphasized that germs swallowed are rapidly destroyed by the stomach acid and the intestinal juices. Infection via the oral route cannot so easily occur, nor is gargling a very effective preventive measure.

Despite all this mass of evidence, discarded teeth continue to rain into the dentist's garbage pail and discarded tonsils to make flames roar in the hospital incinerator.

What, then, may we conclude to be constructive with regard to tonsils?

An editorial in the Journal of Laboratory and Clinical Medicine for May, 1933, said essentially that doctors should not regard the discovery of infected tonsils as sufficient cause to neglect the rest of a complete physical examination. Bad tonsils are potential factors in producing generalized diseases and infections far from their site, but people should not be led to expect miracles from tonsillectomies.

The removal of tonsuls does tend to decrease the recurrence of sore throat, but you can have sore throat without tonsils, and many do. Respiratory infections and most other ailments are about as frequent after as before the operation. Anyway, it takes about ten years fully to demonstrate benefit from the operation in case of serious ailments,

THE removal of tonsils under ether should be regarded as a major operation, always undertaken in the light of its possible hazards and never in the lack of complete justification. Laymen should stop shopping around among doctors, as so many of them do now, trying to persuade them to do an unnecessary tonsillectomy.

Undoubtedly the operation, when its need is properly indicated, can be very beneficial. It is frequently advisable in children but is rather rarely of real value to older people. It is doubtful whether the removal of a focus of infection has a particle of influence on dozens of diseases for which it is done. Practical help occurs oftenest in arthritis, but in case of older people this is too often like locking the barn 50 or 60 years after the horse was stolen.

A person having a lot of tonsillitis and sore throat gets definite benefit from the operation; a person with none gets none. That, according to one of the best informed doctors the writer knows, is the most important thing to remember in connection with tonsillectomy.

prise an intreate assembly of nickel cylinders, do fleeting plates, and a cathod. The cylinders serve to accelerate the electrons and to foun them into a sharp electron beam, to focus the beam on the fluorescent serven, and to increase or decrease the intensity of the beam

The assembly of metal and glass parts is mounted in a funnel shaped glass envelope and scaled in place, as shown on our front cover. A glass tube permits pumping the air out of the glass envelope, this operation taking over two hours for the larger tubes While the pumping operation is being con ducted, the glass envelope is baked in an oven, which is part of the exhaust equipment, at a temperature of approximately 750 degrees, Fahrenheit. This baking drives off moisture which might otherwise remain inside the tube. Another precaution taken to climinate undestrable gases in the evacuated tube is a bombardment of the metal parts, accomplished by slipping heavy coils, carrying high frequency current, about the neck of the cathode-ray tube, so that the metal parts are heated to incandescence through high frequency induction

The construction and assembly of the cathode-ray tube calls for exceptional accuracy in positioning and spacing the parts, since such details affect the quality of finshell tubes. Also, the metal parts must be imbedded in the glass, which calls for great skill on the part of workers familiar with glass working.

MAKE-UP IN DEFENSE

IURID-WHITE "cosmetics" are used by some oil-well and petroleum-pipe-line workers. The oil-workers' facial adornment, however, is put on for defense

Petroleum geologists have discovered many oil fields beneath the waters of the Gulf of Mexico off the shores of Louisiana and Texas. Building a derrick foundation under these difficult conditions made it necessary to use tressords, water resistant in bers. Or we working on and around these timbers soon found that they caused partial inflammation and burns. Pipe-line workers, couring pipes with a black water and corresion resistant, laid the sami muldi.

To protect themselves, they now dank their faces liberally with a zinc oxide preparation that gives them a bizarre appearance but says libsters and infections

SMALL ARC WELDER

A SMALL motor generator type are weld or, said to provide greater convenience and accuracy in welding because of a new self-indicating dual continuous current control, has been announced by The Lincoln Elective Company

Because of its advanced features and motivate price, this must is expected to widen the application of welding in new fields such as garages, how and truck floor repair slope, sheet metal slopes, maintenance departments of pulp and paper mills, paint mills, cement plants, textile plants, gaphans, and smular plants as well as metal.

fabricating shops, piping work, and so on The welder, known as the "A-150," hashoth job selector and current control calibrated and equipped with dials which in dicate the type of work and number of ampères for each and every setting, it is

For accuracy in welding

claimed that this development enables the welding operator to secure highest quality welds and highest possible welding speeds because he can vary both the slope of the volt-ampere curve and the amount of welding current independently and positively to suit every job encountered.

The unit is powered with a "Line-Weld," squirrel-cage, induction type motor for across-the-line starting. Connections are readily accessible for either 220 or 440 volts. 3 or 2-phase, 60 or 50 cycles as desired, the machine can be supplied for 550 volts or special voltages lts current range is from 45 to 200 amperes.

SULFURIO

AIR and water, coming in contact with fron pyrites in coal mines, forms sulfuric acid amounting to about 2.802,000 tons per year, estimates the U. S. Public Health Service Since this water flows outward and pollutes streams, abandoned mines are being sealed up as fast

ENGINEERING COSTS REDUCER

THE tremendous force exerces or the sun does costly damage to curbs and pavements and presents a serious problem to the engineers responsible for the establishment and maintenance of the monuments marking the bies of our city streets.

An accompanying photograph is a view looking down into a manhole in the street and shows how the expanding pavement has moved toward the left, carrying with it the cast iron rim that supports the manhole cover, and crushing the upper course of

It frequently happens that the place for the engineer's monument at the inter-cetion of the center lines of the streets coincides

Even though the pavement moves, reference points of this type remain effective

with what is also the desirable place for a manhole and the likelihood of movement of points set on a manhole cover or in the pave-

ment is well illustrated. The instability of reference points in the curbs and walks at the side of the street is shown in a second photograph. The arrow indicates the head of a spike set in the curb at a catch basin to serve both as a reference point and bench mark Under pressure of expansion the curb has shifted more than an inch to the right, shearing off the wall of the catch basin, and has raised up nearly half an inch, spoiling the value of the spike both as a reference point and as a bench mark

By an original method of utilizing the brick structure of existing manholes, below the pavement, the engineers of the Los Angeles Bureau of Engineering have reduced the cost of maintenance and at the same time increased the stability of the system of points marking the street lines.

Four holes are drilled in the manhole wall and lead plugs driven into them. Brass hooks are then screwed into the lead plugs in such a position that strings stretched between opposite hooks as shown in the illustration will intersect at the intersection of the street

In practice, the manhole cover is lifted and strings or long rubber bands placed on the hooks and the point of intersection used as if it were on the surface.

Painting the hooks with liquid asphalt protects them from corrosion by gases that may be present in the manhole,-Edwin L. Stocking

OXYGEN PRESERVES MILK

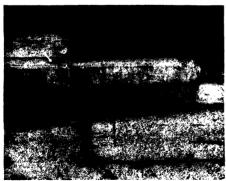

NEW method of preserving liquid milk A NEW method or preserving again and milk products, reported from Germany, consists of holding the milk at low temperature under oxygen pressure -D.

ACID-RESISTANT

BOTTLE CLOSURE

THEIR acid-resistant transparent closure has won for Merck & Company, Inc., honors in the Closure Group of the 1938 All-America Package Competition, sponsored by Modern Packaging Magazine. This same closure also was selected for second award in the Scientific Group of the Third Annual Modern Plastics Competition, conducted by Modern Plastics Magazine.

This prize-winner utilizes an amber transparent polygon-shaped plastic cap, with a liner of impregnated glass cloth. The polystyrene cap is unaffected by the acid contents, and is always casy to remove and safe from leakage or breakage. It is used on an amber "Pour-Clean" bottle, which is named from the special pouring hp which is an in-

A serious problem for engineers: Expansion has moved a curb reference point

tegral part of the bottle opening and 1s covered by the acid-resistant closure

The prize-winning closure was molded by the Mack Molding Company from Bakelite Polystyrene material, supplied by the Bakelite Corporation. The glass cloth for the cap liner is supplied by Owens Corning Fibrglas Corporation; the amber bottle by Anchot-Hocking Glass Corporation.

EXPANSION

BY high pressure hydrogenation, one and one fifth gallons of gasoline is being obtained in the United States from one gallon of oil. This is the highest yield yet attained by any process of treating petroleum.

PRE-TESTING THE AIRPLANE POWER PLANT

PLIGHT testing a lugge flying hoat or a large landplane is a tremendously expensive undertaking because of the powerful engines and the large crews required. Anything that can be done on the ground to shorten the fifth tests is highly desirable, and the Glenn L. Marrin Company has developed an engine test in to achieve such veloped and the state of the contraction of the trated in one of our photographs, it is posuble to determine the operating characteriistics of the power plant months in advance of the trial flights.

The rig consust of a turntable on which is mounted a "mock-up" of a profice no fine he arplane embracing a section of a wing and an engine in its nucelle. In the "observers" balcony" (to the right), located on a level balcony" (to the right), located on a level with the engine, but shielded from it by a wall, are the instruments for recording temperature and pressure conditions throughout the fuel, oil, and cooling systems Our photograph also shows an elaborate portable rig for vibration study, which is an important part of power-plant study. The

propeller is, of course, included in the setup. The turntable makes testing possible with wind from various directions.

The use of the new rig speeds up delivery of a new model by as much as two months, reduces the hours needed for test flying by one third to one half, and fully justifies the somewhat heavy expense of building such a test installation.—A. K

FLASHLIGHT PHOTOS 9000 FEET UNDER WATER

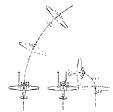

An apparatus able to make flushlight pictures 9000 feet beneath the surface of other the water is the invention of Dr. Hofmann, a leading engineer of Munch. It is a deepsea camera with which he has already conducted successful experiments in the depths of Bodensee, or the Lake of Constance, as a tis known to many American tourists. Thus invention as shortly to be subjected to further tests, thas time 9000 feet below the level of the Tyrthenian Sea between Sardinia and the Istatan manland.

In recent times divers have penetrated farther and father into the depths of the ocean but after they reach a certain depth, the pre-sure of the water is so great that the stoutest diving suits are unable to offer resistance. Dr. Hofmann's deep-sea camera has the advantage that no human being needs to accompany it not the ocean depths. It consists of a chamber nearly 18 inches in divided pounds. The hoff of the properties has three projecting bull's-ryes. A miniature camera is mounted belund the lower window, behind the two upper bull s-ryes is a flash-light apparatus operated by a Cuck-work.

Increasing Flying Boat Maneuverability on the Water

ONLY small seaplanes have water rudders. The large flying boats have none, and the air rudder has but little effect when the flying boat is moving slowly on the water. The maneuverability under such conditions is therefore very poor. To increase this maneuverability when using the present type of non-reversible pitch propellers, the pilot who wishes to turn to the right iddes three engines of the four, and lets the left outboard engine pull him around. The turn is executed slowly and requires a great deal of from

With the Curtiss electrically controlled propeller, it is now possible to reverse the pitch of the blades When the pitch is reversed, so is the thrust. The turn can then

Turning radii of flying boat on water with conventional propellers (left) and with reversible propellers

be executed much more rapidly, as indicated in the diagram, in which the arrows indicate the direction and relative magnitude of the thrust. It is obvious that, with appropriate reserval of pitch, a powerful turning movement can be applied. The pitch reversality may also be employed in shortening the length of the run after alignting.—A. K.

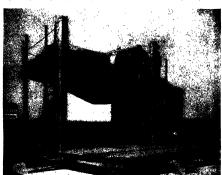

SAFE AIRPLANES

TENTATIVE specifications for private airplanes, intended to secure greater safety, have been assued by the Civil Aeronautics Authority. If these specifications—which are only tentative—are met, the Authority will allow the present dual instruction and solo flying time to be reduced appreciably in obtaining a private pilot's certificate.

The sach shory of the \$700 "diver" airpione has made the industry a trifle skeptical plane has made the industry a trifle skeptical plane has made the industry a trifle skeptical states and the same transport of the same ably safe, that safety is a matter of care in structure of the safety and the same tradeal changes in design or construction are apt to defeat the very purpose of increased safety. We shall not attempt to present the arguments pro and con, but we are convinced that the requirements as set forth have a very spepsing character, and that the majority of them are already realized or could be realized without very much trouble, as seemplisted by the following quotation from the specifications: "Landing and Taxying: (1) The sirplane

onlowing quotation from the specifications:

*Landing and Tarying: (1) The sirplane
shall be capable of being landed easily at
say speed between the minimum and at least
twice the minimum and shall tend to remain
on the ground after contact. (2) Fall application of brakes up to the point of skidding
the tires throughout the entire landing run
shall be possible with no danger of nosing
over. (3) The landing gare shall be stable
in tarying and entirely free from ground
looping tendencies. The sirplane shall be

Airplane power plants are effectively pre-flight tested in this rig

easily steerable. (4) The sirplane shall be capable of being landed over a 50-foot obstacle in a straight glide with no wind and brought to a stop within a horizontal distance of 500 feets. (5) The landing gers shall be capable of satisfactorily withstanding gers whall of the velocity of 15 feet per second, and (b) straight glides to the ground in still air with the elevator control fall back, without overstressing any part of the airplane. (6) The ariplane shall be able to tax in any direction and under complete control in winds up to 30 mp.h."

We believe that these requirements can be readily met by the use of the front nose wheel or "trucycle" landing gear; by bold use of flaps or air brakes; and by designing the shock absorber with a large travel and pow-

criul shock absorbing qualities.

Other requirements call for stability under wared conditions, impossibility of spinning under any conditions, and the provision of only two air controls, one governing the longitudinal attitude and the other for turning, both operated from the same control cultum.

Here we disagree with the specifications. An airplane should be difficult to spin, but it is inconevivable that it should never spin. And a machine which cannot be spin voluntarily may also be hard to get out of the spin. Again, we do not believe that it is so difficult to learn to fly with three controls as to justify sacrifice of the rudder, It is on these aerodynamic or flying requirements.

these aerodynamic or flying requirementthat controver-y is likely to be concentrated. But it would be a great boon if the following "Minimum Field of View" were really made available to the pilot:

"The airplane while standing or taxying on level ground shall permit the pilot an unobstructed level view straight ahead and through a lateral sweep of approximately 90 degrees to each side without moving from a natural comfortable position, and by reasonable movement the pilot shall be able to see the ground within 20 feet ahead of the air-

With an inverted engine of narrow proportions, or a pusher machine, or just good design and plenty of window area, we think that our designers can come very close to securing this degree of vision.—A K.

MEASURING HORSEPOWER

In ariline operation, as much payload as possible must be carried on fast schedule, with the smallest fuel expenditure, and with the least wear on the engine. To check the two last items, the operator should have, at all times during a flight, an accurate record of the power developed by the engine. A number of ways exist for estimation

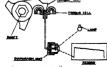

Diagram of a flying torque meter for measuring horsepower in flight

Stearman attack bomber, representative of advanced military practice

ing the power, but none of them is completely accurate. Mr. W. G. Lundquist, of the Wright Arronautical Company, in a paper present defore the Society of Automotive Engineers, advocates the use of a torque meter for this purpose. With such a meter, the power developed by the engular much accuracy as m a test laboratory on the ground.

ning from many ed the frong torque meter share more of our diagrams. This device measures the torque transmitted from the cognite to the propeller. Three "gunder" arms are splined to the propeller shaft; three pressure-sensitive elements are attached to the propeller him fluid, and the fluid pressure generated is transmitted to a measuring disprised more when the first share is small provided murror which reflects a beam of light clum. The way line traced out on the film serves, with proper calibration, to give the exact power of the engine.

The use of a torque meter is but one example of the means which transport companies employ to check their operations —A. K.

AIR CORPS EXPANSION

O IIR readers are no doubt familiar, in general, with the program of Army Arr Corps. By July, 1941, he Air Corps is to have a fighting force of 5500 to 6000 air-plane. Even these figures are lever than those which have been quoted as available ways a question in our minds when the large number of European military simplanes are quoted, as to whether or not out-moded or otherwise inferior craft are included. On the other hand, when the Chief of our Army Air Corps states that he has a certain number of fighting planes at his command, wany he sure that he means ultra-modern machines, the very best of their kind.

In reading the various announcements, one is impressed first of all by the multiplicity of types available. Even towards the end of the World War, training, single-seater pursuit, day bomber, and heavy night bomber paractically completed the classification. Now, further experience in various small wars, and careful tactical studies, have led to a multiplicity of types, each adapted to one, or at most two, specialized purposer—four-engined flying fortresses, heavy bombers, single-engined pursuit, twin-en-

gined pursuits having speeds in the neighhorhood of 400 miles an hour, troop carrying machines, interceptors to stop enemy bombers, multi-place fighters, and so on.

Both military designers and Corps tacticians are as a rule suspicious of airplanes which are to serve more than strictly limited purposes, because it has been found in the purposes, because it has been found in the past that "all-purpose" machines serve all purposes badly. The construction of an "attack-bomber" seems legitimate, however, for combining the high speed and powerful machine gun fire of the attack plane with the bomb equipment of a light bomber is logical enough. One of our photographs ows an attack bomber, the Stearman X-100, recently submitted in a competition in which North American and Glenn L. Martin were also among the participants. The X-100 is undoubtedly representative of the very latest practice. It is powered with two 1400-horsepower Pratt & Whitney R-2180 engines, the gross weight is approximately nine tons, the wing span is 65 feet, and the length is 52 feet. There is a crew of four to take care of navigation and machine gun and bomb equipment. A feature of the new plane is the extreme vision afforded by the transparent panels which make up the entire forward portion. Since ar absolutely mooth skin is imperative at high speeds. flush type rivets are used over the entire outside surface of wings and body. In the design of the machine, an attempt has also been made to combine the ultimate in streamlining with the demands of rapid, large-scale production .- A. K.

STRAW FOR FUEL

RUSSIAN tests of straw as fuel in gas producers have yielded one kilowatt hour by burning three kilograms of straw.

Machine Calculates Timber Volume in Five Seconds

A MACHINE which in five seconds gives the exact volume of a growing tree of any kind and any dimensions, and two other interesting instruments for timber assessments, have been built by a Swedish in-

The "trunk volume calculator," as the machine is called, has been constructed by a Swedish forestry technical expert, Capt. Alvar Drangel of Stockholm, and it has been

considered of such value that the Swedish government has helped finance manufacture and exploitation. It is a "nomo-mechanical" calculating machine, equipped with certain mechanical devices through which a number of scales can be set in relation to each other The machine is, practically speaking, an endless table system, which in five seconds solves an equation after five of its variables have been given exact values. For assessment of the cubic content of growing trees, the machine is thus set for the values of the trunk curvature, the class of bark, the taper percentage, the length of the trunk and, finally, the diameter of the tree at breast height. The volume is then immediately obtained, exact to a ten thousandth of a cubic meter. The machine, which has about the shape of an ordinary calculating machine, but is operated by dials instead of keys, is able to deliver no less than 8,000,000 volume

figures The two other instruments, constructed by the same inventor, are a "trunk diameter registrator," working on the same principles as the first-mentioned machine and of about the same type, and a precision height meauring instrument, by means of which the height from the cut to any desired point on the trunk can be rapidly and correctly fixed The trunk diameter registrator is used for pre-calculation of the quantity of usable timber that can be obtained from a tree By means of it can be exactly fixed the top diameter in eighths of an inch within bark at a certain length from the cut or, the reverse, the log length at a certain desired top diameter - Holger Lundbergh

WORLD'S BEST LIGHTED FIELD FOR NIGHT BASEBALL

WHEN Connie Mack's Athletics and the Cleveland Indians inaugurated night baseball for the American League at Shibe Park, Philadelphia, on May 16, they played

on the best lighted sports field in the world Comprising 780 Westinghouse floodlights of 1500-watt capacity each, the new two-billion beam-candlepower lighting installation is of sufficient intensity to light a street 160

Two-billion candlepower makes this ball field the best lighted in the world. Below. One of the 1500watt floodlights that are employed

miles long as brilliantly as Philadelphiafamons Broad Street; to provide light for more than 2000 homes, to make newspapers readable 175 miles from the light source, if the floodlights were all concentrated in a single unit.

"The Shibe Park infield is 20 times brighter than the average well-lighted office," according to John Kilpatrick, lighting engineer. "It is several hundred times brighter than New York's Times Square on New Year's Eve."

There is no glare and resulting eyestrain for either speciators or players, Mr. Kilpatrick reported This is due to the design of the floodlights and the unusual height at which they are placed. Top rows of lights in eight steel towers surrounding the park are 155 feet above the ground.

Six towers support targets on which are mounted 110 of the big 20-inch floodlights in 10 horizontal rows of 11 lights each. Two others support 60 floodlights in five horizontal tows each containing 12 lights.

Club officials announce that seven night

games will be played at Shibe Park this season by the Athletics, and seven by the Phillies It is also expected that the park will be used for might football games this fall.

MEASURING 2/100,000 of

A MILLIMETER

A REMARKABLE measuring instrument, known as the "Microkator," which is capable of registering measurements down to 2/100,000 of a millimeter, has been invented by Hugo Abramson, Swedish enumber.

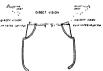

The principle applies a fretinaless gear ugo to measuring instruments, and is remarkably simple. Its unit comprises, in the man, a thin strip of phospho-thorane, twisted around its own hongrudinal axis, half is length in one direction and half in the stationary and an involve point, its center moves in the same way as a triviled yair when pulled A mirror placed at the critical remarks an extremely sensitive indicating device, and when the hand a sirecthed 1/100 of a millimetric, its outsier times 3t digrees using a lever system, will finer readings may be obtained.

The inventor of the instrument, which is manufactured by the Swedsh manufactured and previous measuring instruments, the of the well-known Johansson gage blocks, and previous measuring instruments, the C. E. Johansson Company, of Eddstum, also has a number of other inventors in the precision measuring line to his cited, as also has a number of other inventors in the for example, the heart heart indicator constructed by himself and his brother. Mr Adramson also has received the Gold Medial of the Swedish Academy for Engineering Research—Holger Lundbergh

VISION CONCENTRATORS

T is almost institutive for a person on certam occasions to cup his hands about his eyes the lietter to concentrate his vision on some scine or work before him. There is a definite principle involved in this action Eliminating indirect vision—or underangle vision—gives what is technically called "eenlath haston"—secentrally. "timed vision." In specific seeing tasks, this is advantageous or, since objects in the persplear are shut viewing them is multianeously with those on which the attention is foresed.

A simple device to attain this advantage has been developed by Frederick Saunders

and is being manufactured by the Columbia Protektosite Company. The invention came about as the result of Mr. Saunders' experimental use of two rolled-up programs at a moving picture show. Viewing the screen with them at his eyes started Mr. Saunders on a long study which resulted in the device called Concentrators. They literally congen-

A striking example of a multiple electric motor insullation. Not, just one large motor or several smaller ones, but scores of individual units drive the many rolls on this run-out table at the new Sparrows Point. Maryland, hot-strip mill of the Bettlehem Steel Company, Westinghouse made all the electrical equipment of this plant shich turns out up to 2000 linear feet per minute of strip stred during long runs of tonings

trate the sight and thus enable the user to concentrate more efficiently mentally

Concentrators look somewhat like ordi nary spectacles, but they differ in having no lenses -unless the user needs sight correcting lenses-and in their patented features. To the outer circumference of each eye piece there is molded a small opaque rim flange which projects forward and cuts down the angle of vision from side to side Projecting backward from the same rims, are shieldwhich cut off all side light. The result is that all distracting side vision is completely eliminated. The effect is so marked that Dr Martin Crabau, former Harvard Uni versity physics professor, after testing and approving Concentrators, remarked that it was amazing how much could be accomnlished so simply

Concentrators will be useful for students, stenographers, golfers and other sportsmen, theater-goers, and all those who must concentrate on work in hand.

GROWING TOBACCO WITH-OUT NICOTINE

REPORTS from Italy state that tobacco with a total classes grafted on tomato plants grow with a total disappearance of nicotine Leaves normally containing 2 to 2.5 percent mouture were used in the experiments and lost all their nicotine content without having it appear in the leaves of the plant to which the graft was made—D H. K.

"PULLMAN" FOR GIANT SALMON

TRUCKS are built these days to perform most any transportation job you care to name, but few are designed for a purpose as unusual as a feet of eight recently ordered by the U.S. Bureau of Reclamation.

These are to carry thousands of giant salmon, 30, 40, or 50 at a time, alive and undamaged, to destinations they never would reach manded. The fish will travel in 1000 gallons of Columbia River water, constantly aerated to supply the occupants with adequate oxygen, protected by insulation against outside temperatures ranging from 108 degrees down to 30. In transit, the salmon compartment will be cooled gradually to prepare the occupants for the chill waters of Wenatther River and feeled Teck, Cracked rec, weighing 1800 pounds, is carried in a special compartment for this purpose.

Extraordinary precautions are being taken to keep the motoring fish comfortable and unhurt. Every inside contour of the tunks is to be smoothed, and they are designed so as to fill to the brim, since the salmon must not be hanged against the sides by sloshing water. Specifications demand a 50-mile top-peed with a gross load of 25,000 pounds. The job is an important one, affecting the

future of a great industry.

Up the Columbia River each year moves the greatest salmon run in the world, some three million fish, Chinook and Steelhead, bound for the headwaters to spawn and start.

the life of a new generation. The parent fish die but tiny youngsters go down to the coean to grow. Five years later, averaging 22 to 30 pounds apiece, these splendid salmon retrace their way upstream to their native

A \$15,000,000 a year industry depends upon the continuance of this vast migration, but its way now is disputed by power dams built to harness the vast energy of the turbulent hurrying river. Millions have been spent to build fish ladders to get them spent to build fish ladders to get them pents built in the sea the way is blocked.

The task given the eight fish "limousines" is collect the salmon whose insture heads them to the streams above Grand Coulee, and carry them to other, unblocked trabutaries. It will not be an easy job From July to the end of September, the run will be at its peak, and fish trucks will have to be on the go all the time, emplying the fish traps, or all the grand that the strength of the strength of

ALCOHOL ANTISEPTIC FOR WAR-WOUNDED

HOW wardorn Spain became the proving ground for a new type of alcohol anti-septic vs revealed for the first time in Military Surgeon, official publication of the U. S. Association of Military Surgeons. Adding weight to the report is the fact that its author, Major S. Petez-Vasquez, M.D. was physician in charge of the famous Howpital de Carabineros in Madrid.

The new alcohol antiseptic which Dr. Perez-Va-quez found to be the "most satisfactory of any preparation in general use" may have even wider application in peace. He writes that, on war wounds of all types,

Special truck designed to carry giant salmon, alive

it not only controlled infection with less discomfort to the patient, but also speeded healing and shortened the period of hospitalization.

"Even when . . . used several hours after injury, a quick drop in fever is observed, and within four days after beginning treatment. healthy granulation tissue appears. Much less operative surgery was required."

The new antiseptic-a mixture of ethyl alcohol, glycerine, thymol, phenol, and camphor-was evolved by Dr. Perez-Vasquez and his associates in an effort to find a solution which could be used with simple irrigation in place of the cumbersome technique a specialized apparatus of the Carrell-Dakin

It was perfected, Dr. Perez-Vasquez states after a careful trial of other approved and generally used antiseptics including jodine and several proprietary products

The article in the Military Surgeon gives

the formula and directions for compounding the solution

A Professor's Scientific Pipe

W/HEN science invades the sanctity of man's popular pastime of pipe smoking, the result is a highly-engineered job which offers convenience and satisfaction to the smoker. Latest evidence of this fact is

the scientifically-designed pipe invented and perfected by F. K. Kirsten, professor in the school of Aeronautical Engineering at the University of Washington,

An enthusiastic pipe smoker himself, Prof Kirsten set about to apply engineering prin-ciples in developing a pipe that would elimmate the objectional features ordinarily associated with pipe smoking.

The Kirsten pipe is based upon effective cooling of the smoke so that undesirable oils and tars, which are in volatile form, are removed by condensation before reaching the smoker's mouth. To obtain efficient cooling, a unique stem, or barrel, is used It is made of aluminum alloy and has a characteristic high heat conductivity supplemented by an efficient fluted design which increases the rate of heat dissipation.

In order to allow ample time for the smoke to cool completely, the volume of the radiator has been precisely determined so that it holds the equivalent of the average smoker's puff, or from six to twelve cubic centimeters. Because of the radiator's volume, the gases can remain in it for the duration of and the interval between puffs. Experiment has shown that this period is long enough for the com

plete cooling of the smoke and to permit the esirable contents to condense.

The condensed tars and water vapor collect in a small radiator cap, also of aluminum alloy, at the lower end of the harrel—the lowest point of the pipe when in the smoking position. Their flow back into the bowl is prevented by a valve mechanism which is incorporated in the radiator cap. By giving the cap a right angle turn, the valve closes the bowl outlet, and the pipe can be turned upside down to discharge ashes. The condensate is securely trapped in the radiator

Left: The scientifically designed pipe has an aluminum stem, Above: Each part of the pape is designed to accurate engineering specifications. Parts are interchangeable. Right: The same principles have been applied to a cigarette holder

and none of its odors can escape. The radiator cap can readily be removed to empty the condensates.

The bowl of the Kirsten pipe is detachable, being held in place by a double-lotted alu minum alloy screw which forms the bottom of the bowl. This feature permits the smoker to interchange the bowl with any one of a arrety of stock shapes and sizes available The inner walls of the bowl are sloped to give the most efficient combustion of the tobacco. It was found that the most uniform burning was effected by shaping the sides of the bowl so that they formed an angle of 13 degrees with the vertical.

An aluminum ramrod is attached to the intake tube fitted in the mouthpiece and serves as an aid in cleaning the pipe by running a piece of tissue paper through the ra-diator, an action not unlike cleaning the barrel of a gun

The pipe is 10 to 50 percent lighter than

the conventional design pipes.

The scientific principles of the Kirsten pipe have been carried a step further in the Kirsten cigarette holder which also cools (and cleans) the smoke through radiation from a finned aluminum alloy stem

DIPHENYL SAVES PALES. TINE'S CITRUS INDUSTRY

LONG distance shipping of Palestine's citrus fruit crop is made possible by wrapping it in impregnated paper. Losses by spoilage are reduced by this method to approximately 10 percent of their forme value. Diphenyl is used to impregnate the wrapping paper and this in no way affects the odor, taste, or appearance of the fruit. This method may save the citrus fruit industry of Palestine by permitting the eco nomical export of its product to remote markets in north Europe.-D. H. K.

SELF-ADHESIVE LABELS

SELF-ADHESIVE labels, manufactured by Avery Adhesives, costed on one side with a non-drying gum, will adhere to any smooth hard surface without leaving any stain or gummy residue no matter how long they are in place. These Kum Klean labels can be used for marking glassware, silver, office supplies, pottery, china, toys, furni-

INSECTS versus WEFDS

TINY Argentine moth has saved a A large part of a continent from being turned into desert by a predacious plant which was devouring more than 1,000,000 acres a year, literally driving farmers out of their houses, and resisting attacks with liquid fire. The plant is the prickly pear, a species of cactus common over the United States, Mexico, and South America, and which is often grown as an ornamental in

Nearly a half century ago a few plants were introduced into Australia from North America, intended for flower gardens. The prickly pears found themselves in an earthly paradise where they could run wild with nothing to stop them. By 1925, they had

covered more than 60,000,000 acres in Queensland and New South Wales, Most of this had been good grazing and farming land. About half of it was in the grip of a dense jungle of cactus from three to five feet high and so thick that it was impenetrable. The other half was covered by less dense

Just when the problem seemed unsolvable, salvation came in the form of the little Argentine moth. Australian entomologists had unted all over the Americas for insects which might help get rid of the cactus. Many type specimens were studied in the collec-tions of the Smithsonian Institution. The majority of them, it was found, did no real good. Their larvae ate the cactus, but the plant was too tough to be killed by them. The Argentine moth, however, displayed life habits which admirably fitted it to rescue a continent.

The Australian entomologius tell of one stretch in Southwest Queensland where the prickly pear extended in a dense, almost continuous belt for 100 miles. A most colony was planted in this neighborhood. A year later the entomologius were in despair. The nesets seemed to have done no good whatsever. But another 12 months and the whole jungle land simply collapsed. At least 90 percent of the plants were destroyed and the cent of the plants were destroyed and the Allogather the insect has reclaimed more than 15,000,000 acres to date.

SULFANILAMIDE FOR SMALLPOX?

THE new drug sulfanilamide appears to have value in treating smallpox. Four cases in which it largely prevented the cruption from the disease are reported in the Journal of the American Medical Association by Dr. Walter O. McCammon of Springfield, Kentucky.

Seven cases of smallpox recently came under the observation of Dr. McCammon He
used sulfanilamde in treating four, and
there was only as slight cruption which soon
diasppeared. The patients were back at work
a week sooner than were the other three
cases which were treated symptomatically
and in which the typical eruption of smallpox
developed.

In an editorial, the medical journal points out that no conclusions as to the value of sulfanilamide in preventing deaths from smallpox can be drawn from such a small number of cases

Although smallpox is increasing (there were 14,355 cases reported last year) the disease is now mild —Science Service

SEED GERMINATION WITH

NATURE'S way with seeds has always been hard to figure out—a hit-and-miss proposition largely based on guesswork. But the Peppard and the Rudy-Patrick Seed Companies of Kansas City, Missouri, have

Below: The air-conditioned unit for seed germination and, right, shelves on which seeds are placed

Gold in an automobile factory may seem incongruous, yet in the Rouge plant of the Ford Moor Car Company it does a "laborar" job of expediting the during of enumels with which motor-ear parts are coured. (See all Sprinting the May, 1993, page 2535. This striking photograph shows one of the tunneds through which bodies are drawn, after painting, to be dried rapidly by the infrared rays from a battery of lamps. These lamps are backed by reflectors, the surfaces of which are gold plated, since it has been found that such a surface most efficiently concernates the desired rays on the automobile bodies.

eliminated the guesswork and reduced the whole process to a science. They employ the use of seed germination boxes to test the growing ability of all varieties of field grasses, and garden seed. In this way, Mother Nature's future whims are accurately prognosticated.

A given number of seeds from any one lot is placed on moist blotting paper and inserted in the germinating box. Within the box, it is imperative to hold the relative humidity at 90 percent and to maintain tem-

planted the first thing in the agring, such as radules, lettuce, afalfa, and clovers. These do not require as much heat to protest and, for the control of the control of the control the germantor which maintains a constant importantor of 60 degrees. It is for this reason that each germantor is constructed with two compartment—one equipped only with refrigeration and the other with both refrageration and an electric stip heater.

The Creamery Package Manufacturing Company of Chicago, through its Kansas City office, furnished these Trane germinating units.

perstures which correspond as nearly a possible to the temperstures to which the seeds would be exposed in the fields during their planting or sprouting period. This tempersture, of course, varies during the 24-hour daily cycle. Therefore, in the germinator, varying temperatures are maintained—namety 68 degrees for 16 hours simulating the night, and 85 degrees during the eight hours corresponding to the smallgst corresponding to the smallgst cycle.

Of course, there are seeds which must be

INDUSTRIAL USE OF

FROM 1932 to 1938 the United States imports of crude papans increased approximately four-fold to 223,000 pounds. This mately four-fold to 223,000 pounds. This cruyme is the dred milky junc obtained from the skin of the unripe papays, which from the composition of the unripe papays, which throughout the world. Aside from its value in medicine as a digestive, papain is used to make tough met tender and has a sixiliar and effect on other foodstuffs. Although papays grow in Florida, Texas and California, the chief American supply of papain comes from Ceylon—D. H. Texas and California, the

Non-Shock Treatment for Mental Disease

M ENTALLY sick patients are now being rescued from the world of the insane by the simple and comparatively safe measure of breathing nitrogen, it was announced at a recent meeting of the Federation of American Societies for Experimental Biol-

"Encouraging results" of this new, non-

shock treatment for insanity in a small series

of cases were reported by Drs. H. E. Him-wich, F. A. D. Alexander, Basile Lipetz, and

J. F Fazekas, of Albany, New York, Medical (ollege and Union University, The new treatment achieves its effect by

the same mechanism as the drastic insulin and metrazol shock treatments. This is by

decreasing the metabolic activity of the

brain. The nitrogen inhalation treatment, however, is easier to give than insulin shock

and does not produce the fearful convulsions of metrazol treatments which are dreaded by both patients and physicians. With the new treatment, patients breathe nitrogen long enough to deprive the brain of its oxygen supply for about five minutes These treatments are given three times a week for a period of about three months. Cutting down the oxygen supply to the brain reduces its metabolic activity Metrazol does the same thing by temporarily ar resting breathing movements. Insulin shock

does it by depleting the sugar supply to the

brain, without which the brain cannot use

The fact that metrazol and menha-shock

treatments both produced this effect of de-

creased metabolic activity was discovered a vear ago by a University of Toronto research team under the leadership of Sir Frederick

Banting and Dr G Edward Hall, At that time Dr. Hall predicted that neither insulin

nor metrazol would be the last word in treat ment of schizophrenia and that a better and

less severe remedy would be found to replace them The nitrogen inhalation treatment seems now to be that remedy -- Science

\$39.50

AUONG the manufacturing operations performed on aluminum allows, none is more interesting and spectacular than the impact extrusion process. By this method, a small biscuit-shaped slug of aluminum is transformed in the twinkling of an eye into a tooth paste tube, a flashlight case, or any one of several hundred commonplace containers and shapes

ALUMINUM IS SOURTED

The moving head of an impact extrusion press is fitted with a punch or hammer which is slightly smaller in cross-sectional dimensions than the stationary die The slug of aluminum is placed on the die, the hammer strikes the slug, and the high pressure forces the aluminum slug to "flow" up past the clearance between die and hammer, thus forming a collapsible tube or any other shape determined by the die The metal is literally "squirted" into the desired shape.

Pieces and containers of various size shapes, and intricacy of design can be formed at high speed and low cost by the impair

A slug of aluminum is in the

The aluminum is squirted

extrusion process. Many parts ordinarily made by drawing, spinning, stamping or turning can be produced to advantage by this method. The chief advantages to be obtained by adopting this process are closed min-risonal telerance, a high degree of uniformity in parts, and surprisingly low producing early.

By the nature of the impact extrusion process, the metal is strain-hardened, devel-

... and a formed tube results

oping its strength and stiffness. Thermal treatment may be used to anneal the finished product for the softness necessary in collapsible tubes or the parts may be given even higher strength by controlled heat treatment. Thus, various properties are at the option of the designer.

There are almost no limitations on the shapes of impact extrusions. Symmetrical and baseaulty sylindrical forms are the bessuited to the process, but square, oval, revtangular, and ssymmetrical parts can be made rapidly and allow unit cot. The wall thickness of parts can be varied from their without the control of the control of the wall at points of stress and strain to this natural light weight of aluminum is added the advantage of less metal where not needed

BEWARE! TICKS CARRY SPOTTED FEVER

CONSIDER all ticks dangerous, advises the U. S. Public Health Service, even though only one in 300 of the eight-legged pests is capable of transmitting spotted fever, in the most heavily infected areas.

Although the exceedingly dangerous techorne disease was first found in the west, whence its name of Rocky Mountain spotted fever, it is now known to exist eastward to the Atlantic, as far north as Massachusetts, and as far south as Georgia.

If you live where ticks abound, or if your dog brings them to the house after cruising in the brush, better examine yourself all over at least once a day. If you find a tick has taken hold, remove him with a pair of

WHERE SCIENCE ENDS HOSPITALITY BEGINS

The Waldorf, for example, is a magnificent scientific achievement, not only dependent on science when it was built, but continuously dependent on many sciences for the efficiency of its operation.

But every man of scientific turn of mind knows what we mean when we say that hospitality, in his own home no less than in the Waldorf, is something warm, lynng and human that survives scientific detachment.

And it is that ability to preserve the human touch, in spite of all our clockwork schedules and efficiency, that gives the Waldorf its unique reputation for maintaining close, cordial and communicable contacts with its patrons.

Besides, this year, when you come to New York, you'll get so much science at THE FAIR, that it'll be a genuine relief each day to return to the hospitality of The Waldorf-Astoria!

tweezers or a small piece of cetton or paper, being careful not to crush it. Tick "tuice" can be very dangero

can be very dangerous.

Drop the tick in kerosene or gasoline, to kill it. Swab the bitten spot with iodine, and dip your fingers and the forceps in alcohol or wash them thoroughly, the Public Health Service advises. It is highly advisable also to "de-tick" your dog at frequent intervals, with the same precautions —Science Service.

INKLESS RECORDING

INSTRUMENTS

ONTINUOUS accurate operation for 30 days without attention, at temperatures as low as -10 degrees, Fahrenheit, and as high as 120 degrees, Fahrenheit, is made possible by the new Type CF-1 line of inkless recording single- and double-range A.C. ammeters and voltmeters just announced by

the General Electric Company. The units are in the low-price range and are particularly well suited for voltage surveys, complaint investigations, and checking circuit load conditions. The inkless mechanism, which uses a typewriter ribbon to make the record by a series of dots, results in greater simplicity. small size, and light weight. There is no inkwell to clean, no pen to start, and nothing to freeze in cold weather. A cast aluminum alloy case protects the mechanism and further suits the new instruments for service while exposed to the weather. Although they are portable, the new instruments may be wall- or pole-mounted

FLAMEPROOF FABRICS

THE opening of San Francisco's Golden Gate Exposition emphasizes the usefulness of flameproofed fabrics. More than 200,000 yards of decorative materials have been treated with fire retardant chemicals to reduce the hazard of fire. The chemical used, ammonium sulfamate, does not affect the decorative beauty of the treated fabrics. Although the San Francisco Exposition was the first World's Fair to open using flame-proof fabrics throughout, the New York World's Fair imposed similar regulations. —D. H. K.

FACTORY PRECISION

ON'T believe it if someone tells you that DON'T believe it it someone tems you company-ing illustration, is sighting his bow and ar-row for a bull's-eye shot at a target. The bull's-eye at which he is "aiming" is the measurement of any difference between the

Determining expansion coefficients

expansion coefficients of metal and glass. In the manufacture of vacuum tubes, insulators, and other electrical products, metal and glass must be scaled together to withstand varying temperatures, and it is through this tele-scopic "sight" that Mr. Burger determines expansions as small as ten millionths of an inch in the Research Laboratory of the General Electric Company

WELDED HACK SAW BLADES

HIGH efficiency is the claim of the Arm-strong-Blum Manufacturing Company for its Marvel high-speed-edge hack saw blades They are manufactured by uniting a high-speed steel tooth edge with a supporting body of chromium vanadium steel. The two parts are integrally welded by a patented electric welding process

It is claimed that the high-speed steel edge provides all the fast-cutting and longwearing qualities of good cutting tools, while the body of chromium vanadium steel contributes exceptional strength.

ELECTROPLATING WITH A

SMALL repair shops and home workshops can now have their own electroplating equipment. An inexpensive kit recently put on the market by the Rapid Plating Process, Inc., enables the shop or home user without previous experience to electroplate individual articles or worn spots on various ob-

The plating is done with a specially designed brush through which an electric current passes. Only one or two dry cells are required. The plating compound is of a jelly-like consistency and contains, in a highly concentrated form, the metal to be deposited. This compound adheres to the surface being plated without spilling or running. Objects even in overhead positions may be plated without dismantling or loss of time from

It is claimed that the quality and permanner of the platings are equal to com-mercial platings, thickness for thickness. Nickel coatings of 1½ to 2 ten-thousandths can be successfully deposited with a com-

CVERY important discovery relating EVERY important discovery relating to mind power, sound thinking and cause and effect, as applied to self-advancement, was known centuries ago, before the masses could read and write.

Much has been written about the wise men of old. A popular fallacy has it that their secrets of personal power and suc-cessful living were lost to the world. Knowledge of nature's laws, accumulated through the ages, is never lost. At times the great truths possessed by the sages were hidden from unscrupulous men in high places, but never destroyed.

Why Were Their Secrets Closely Guarded?

Only recently, as time is measured: not Only recently, as time is measured; not more than twenty generations ago, less than 1/100th of 1% of the earth's people were thought capable of receiving basic knowledge about the laws of life, for it is an elementary truism that knowledge is power and that power cannot be entrusted to the ignorant and the unworthy.

Wisdom is not readily attainable by the Wisdom is not readily attainable by the general public; nor recognized when right within reach. The average person things, but goes through life without ever knowing where and how to acquire mastery of the fundamentals of the inner mind—that mysterious silent something which "whispers" to you from within.

Fundamental Laws of Nature

Your habits, accomplishments and weak-nesses are the effects of causes. Your

and sleeping. All fixed laws of nature are as fascinating to study as they are vital to understand for success in life.

vital to understand for success in life. You can learn to find and follow every basic law of life. You can begin at any time to discover a whole new world of interesting truths. You can start at once understanding an of self-advancement. You can learn from one of the world's oldest institutions, first known in America in 1694. Enjoying the high regard teachers, the order is known as the Rosicrucian Brotherhood. Its complete name is the "Anchent and Mystical Order Rosse Crucis," abbreviated by the information of the control of tials "AMORC." The teachings of the Order are not sold, for it is not a commercial organization, nor is it a religious sect. It is a non-profit fraternity, a brotherhood in the true sense.

Not For General Distribution

Sincere men and women, in search of the truth—those who wish to fit in with the ways of the world—are invited to write for complimentary copy of the sealed booklet, "The Secret Heritage." It tells how to contact the librarian of the archives of AMORC for this rare knowledge. This booklet is not intended for general distribution; nor is it sent without request. It is thereis it sent without request. It is there-fore suggested that you write for your copy to the Scribe whose address is given in the coupon. The initial step is for you to take.

Experimenters - Schools - Field Workers

An Accurate Balance at a Price Within the Reach of All

Weighs up to 100 grams Compact-No loose parts Modern, durable construction Small convenient size Handsome streamline design Now normissible for auxiliary use in drug stores (N. Y. C. Serial B17.)

Sensitive to 2/50 gram

Never before a balance with all these exceptional features!

Finest Quality—Made of tested materials. Its construction will appeal to laboratorics desting the best equipment. The Bakellie cup lumaffected by practically any substance that can come in contact with it the tool steel killer edge and agate hearing will give long 106 and accuracy.

I trem. Senativity.—Weighs to one decimal point farther than the usual low-pried counter scales and serves nearly every labora, tory purpose short of prieds analysis. The capacity of 100 grams is ample to: the delicate

weighings made in the usual course of teach-ing organic synthesis experimental work, compounding photographic work etc.

Compact Convenient - Does not monopolize laboratory table Placed on the desk of bury technical executive it will soon been indispensable

Its small size makes it possible to carry it on inspection and testing trips at a distance from the laboratory It1 small enough to be carried under the arm or in an overcost

Graduated in either the Metric System (grams) or the Apotherary's System (grains drams and conces). In ordering, press indicate which of these yes desire

SCIENTIFIC AMERICAN, 24 West 40th Street, New York

paratively few brush strokes, Cadmium 2 to 4 ten-thousandths and silver 1 to 10 tenthousandths can be deposited, depending upon the time expended in the operation. Other metals which can be plated by this method are gold, copper, tin, and zinc.

The process is not designed to replace the ommercial method of electroplating but rather to supplement it. The brush method is particularly useful for miscellaneous small jobs and for touching up small areas which are not subject to heavy wear.

ICE

APPROXIMATELY 15 million tons of ice-enough to make 240 billion average-size cubes-are required annually by the American railroads to keep freight and passengers cool. The great bulk of ice purchased or manufactured by the railroads and refrigerator (ar companies-nearly 13 million tons of it goes in what have become known as "America's rolling refrigerators.

SOUEAKING RUBBER

THE problem of the squeaking rubbermounted spring shackle is an annoying one for motorists. Oil should not be used as a lubricant because of possible softening of the rubber, and brake fluid affords, at best, only a temporary remedy A satisfactory lubricant is made of colloidal graphite in glycerin and water, reports B H Porter, of Acheson Colloid Corporation Glycerin has desirable characteristics as a rubber lubricant and it increases the retention of the graphite by the lubricated parts. The water acts as a carrier and soon evaporates.

CORN COR LIGNIN SOFTENS CITY WATER

N their search for some practical use for IN their search for some practical was and bignin, one of the principal waste products of the country, chemists have discovered that recovered lignin is more effective in treating hard water containing iron than commercial compounds now in use

At the Agricultural By-Products Laboratory. Ames, Iowa, chemists of the U. S. Department of Agriculture treated hard city water, hard well water, and water containing added iron with lignin prepared from corn cobs and found this material to be effective as an iron-removal agent.

Supplies of lignin are inexpensive because they are almost limitless. Roughly, one fourth of all wood plants, including trees, is lignin. As a waste product of wood pulp mills, where its disposal pollutes streams, it amounts to about 1.500,000 dry-weight-tons each year. At least six million tons a year is available from corn stalks and an equal quantity from wheat straw. Other extensive supplies are cottonseed hulls and sugar cane bagasse-the fiber remaining after the juice has been squeezed from it

In treating water that contained about 36 parts per million of iron with 500 parts per million of lignin, the iron content was re-duced to an average of about two tenths of one part per million. The lignin was recovered and used again up to 10 times with no appreciable lessening of efficiency. The same

amount of an inorganic compound commonly in use reduced an identical iron content to only one and one half parts per million for the first six times it was used and thereafter rapidly lost its ability to remove the iron. The cheaper lignin powder not only removes more iron, but can be recovered and used more times

Many cities may find it possible to use the lignin treatment with existing water filtration plants by adding the recovered lignin to the water in the mixing and sedimentation tanks, or applying it as the water enters the filters where earliers are used for odor removal

REVOLVING MULTIPLE. SCALES FOR METERS

ON the measuring instruments of the present day with several measuring ranges, it is necessary to multiply the results by a given factor which has a different magnitude for each measuring range. These calculations not only entail waste of time, but they are a source of possible errors, and this, of course, means that they may constitute an

Above: Flexible multiple scale for meters, Belou Several rows of numbers on a conventional meter scale

element of danger for apparatus through which current flows. The difficulties are peculiarly serious in the case of several scales with varying characteristics.

The elimination of all calculating work, when using electric measuring instruments, can be made possible by introducing suitably divided and numbered divisions into the scale-field for each measuring range; on the other hand, it must not be necessary that a measuring range represent a given multiple of another range. This problem has been solved by the Toroid Multiple Scale. A rope pull, or toothed-wheel, coupling between neasuring-range selector and multiple scale effects a positive change-over of the scale, along with the change-over of the measuring range, with the result that all risk of confusion is eliminated.

One of our illustrations shows the construction of the new revolving multiple-scale. A flexible roller, preferably a seamless foldtube in spring-bronze, is arranged to revolve on an axle which is curved to correspond with the form of the scale as it must appear behind the window of the case. It is coupled

L. S. TREADWELL & CO., INC. INDEPENDENT & UNAPPILÍATED ADVISERS 116 JOHN STORET NEW YORK with the measuring range selector which is constructed in the form of a rotary switch. Surrounding the flexible roller, an elastic sheathing in either cylindrical or prismatic form is firmly connected with the fold-tube. and on this the numerals or divisions are marked. Thanks to its unique construction, the fold-tube has been found quite torsionproof. It can be driven from one side, without twisting and there will, consequently, be no distortion of the divisions. The cylindrical revolving body is used when several rows of numerals must be interchangeable, while the prismatic form will be selected when not only numerals but also complete divisions must be changed

INVENTORS KEEP AFTER ATTO IMPROVEMENTS

NE in five of the 43,000 patents granted by the United States during 1938 had an automotive application

A total of 8268 of the patents granted related to the motor vehicle in some fashion Not all affected the mechanical or exterior design of the car itself, many dealing with manufacture and repair, with parts, acces sories, lubricants, fuels, as well as special machines and processes usable in car production

Of these, only 349 were issued to automo bile manufacturing companies. The automo tive patents represented an increase of 1004 over the number granted in 1937, while the total volume of all patents granted was only

RUBBER PAINT

A PAINT containing a rubber hydro-carbon is said to be especially suitable for chemical laboratories because it is not only decorative but also resistant to acids. alkalies, fumes, and moisture, according to the Fisher Scientific Company Other claims are that the paint will not crack or peel at temperatures up to 350 degrees, Fahrenheit, and that it can be applied to wood, metal, plaster, concrete, or brick Plicote, as the paint is known, is available in ten colors and white

COMPOUNDED WOOD IS NEW MILLING ADVANCE

THE old practice of veneering furniture, which turned out a mahogany table for five dollars, is back in a new and much more fundamentally important form.

Compounding wood, as the process of veneering is known to the trade, is now turning to the new field of making wooden beams which have all the uniformity of characteristics of steel and other metals Do you wish a wood with a given density, a given elastic strength and other properties Compounded wood is the answer and each time you place an order with the mills it comes through the same, time after time.
Wood unsuited for many construction

purposes becomes the core of the plank and laminated layers supply the exterior. The proportions of each are varied so that the same characteristics can be repeated at will.

In part, the use of phenolic resins as the gluing agent in the finished board is the difference between older veneer panels and the new beams of technologic mill working. The various layers of wood are arranged in Established 1853

Are You

putting your spare time to good advantage?

one of the many who are seeking a new field to en-

secking a means to save money wherever possible?

If you are, here is a practical solution to your problem.

HOPKINS' CYCLOPEDIA OF **FORMULAS**

Is the foundation for the beginning of a fascinating hobby; the groundwork on which to build a practical knowledge of useful chemical facts.

Is the foundation for hundreds of suggestions for those who are seeking salable articles which can be manufactured at home profitably on a small scale.

IF you want to save money on wines and liquors; your dyes, inks, polishes, soaps, paints and varnishes, adhesives, antiseptics, bleaches, cosmetics, etc.

You can profitably make them from the 15000 formulas contained in the 1077 pages of

HOPKING

Cyclopedia of Formulas \$5.50 postpaid (domestic) For sale by

SCIENTIFIC AMERICAN 24 W. 48th St., New York City, N.Y. "books." dried, coated with the resin, heated

"books," dried, coated with the resin, heated electrically, and finally pressed at proper temperatures into finished lumber.
"These hoorts," states the Industrial Bulletin of Arthur D. Little, Inc., "meet predetermined specifications, with widths previously unavailable, and with a uniform adherence to specification comparable to that of the steel construction industry."

The resig used in the process impregnates the board with vapors which are obnoxious to fungi and thus the long-sought fungusproof board is at hand .- Science Service.

"SCREW-SOCKET"

FLUORESCENT

THE accompanying photograph shows a THE accompanying protogram new type of fluorescent lamp, which may be screwed into the conventional electrical socket without special installation or wiring. as completed by the Duro-Test Corporation. The new lamp will be marketed for commercial lighting as well as for certain types

The new fluorescent lamp, at top, and its havenet joint sarew socket

of domestic illumination. It is estimated that all fluorescent lamps reduce current costs about 80 percent to give light equal that provided by the incandescent type of lamp. The tube itself, when it burns out, can be detached from the starting device which forms the part which screws into the socket. In addition, Duro-Test's new fluorescent starting device uses only 212 watts

BIRDS OF PREY MAY CARRY BUBONIC PLAGUE

Bt BONIC plague, like other forms of death in these days, has apparently taken to air travel. Not on the man-made wings of airplanes, but on the wings of hawks, owls, crows, and other predatory and scavenger birds, says the U. S. Public Health Service.

The suggestion comes from William L. Jellison, assistant parasitologist at the Rocky Mountain Laboratory of the Service. Thirty years ago, Dr. W. C. Rucker made a similar suggestion, but limited it to one species of burrowing owl that shares habitations with ground squirrels and other rodents that car-ry fleas which are in turn the ultimate carriers of the plague germs. Mr. Jellison, however, greatly extends the list of suspected birds, to include two species of hawks, two of falcon, three of owl, and one species each

of eagle, magpie, and crow.

All these birds prey abundantly on the plague-carrying rodents. The scavengers, like crows, devour their catches on the spot, but predators, like hawks and owls, carry the carcasses to their nests, with the possibility of distributing the fleas either on the way or after they arrive. In several cases, these flesh-eating birds were observed in attacks on rodents dead or dying of the plague .--Science Service.

CAVIERA INGLES

Conducted by JACOB DESCHIN, A.R.P.S.

SIMPLIFY YOUR TABLE-

THE art of table top photography is comimmally stress do photography writeras being one of the simplest of camera rediavors. Frequently, however, these same writers deliberare be contradict the med best by introducing methods and illustrations not casely within the reach of the average ample exercise when discussed from the point of view of the annation worker. The truth is offer the properties of the properties of the prolate when the properties of the prolate when the properties of the p

But, for you and me, table-topping meansomething else again. It means, actually, a clear space on a table upon which are arranged a number of simple odds and ends either found around the house, purchased in the five and-ten-cent stores, or if you are at all hands, made by yourself.

at all hand), made by yourself Your principal difficulty will be in proyourself, so much the better, but most of is cannot However, the little iron and other toy figures in the stores will usually do the trick admirably.

Another feature of table top set-ups is the question of furniture Occasionally it is possible to pick up miniature reproductions of furniture pieces, but the best procedure is

to make the furnature yourself. This is not as difficult as it may sound Ordinary card loard will often seve the purpose and a codium may cashly be simulated with a small cardboard mailing tube or even a sheet of paper terester format and held together with a step of adhesive. An excellent medium for immuture furnature making is balss wood, now obtainable in home craftsman packages, compressing an essentient of

Above: Making the set-up for "The Shadow of the Law," as described in the text and, below, the result

halsa wood in several thicknesses and

lengths.
"The Shadow of the Law 'illustrates what can be done with a couple of ron figures bought in the five-and-ten-eral store. These consisted of a polereman and a strolling pedestrian. The objective was to arrange in a simple manner a street seene showing a polereman, whose body cast a long shadow down the sidewalk, while a civilian approached lum from the opposite direction.

Set-up for "Performance"

A piece of cardboard was wored with a perkinfe at one inch intervals over a space about four inches wide, and a strip of black. Notich tight separated this portion from the rest of the cardboard. Thus, when the light beam was directed at the low angle necessary for the projection of the long-shadow, these depressions caught the light in charreflect of separating grooves between the "stone slabs" of the sidewalk.

In order to complete the impression desired, no effort was made to continue any further in the matter of a set up other than to provide a black wild beyond the sidewalk edge. This was done by placing the cardboard on a black cloth and so arranging the light that very little of it reached this cloth. The spotlight used to illuminate the subject.

Municated by one large candle to down left of figure. No other illitization was entabled for this

"Performance"

was, therefore, cut down in beam size through the use of a price of cardboard in the center of which a hole was cut of approximately the damatter required to bring about the desired limitation of the illumnated area in order to throw some light into the face of the policeman a reflecting series over with silver foil was placed as shown. This caught some of the light, and, by suitable angling of the series, brought a little light onto the front of the policeman's figure that otherwise would have been dark. With the less stopped docconsiderably, the exposure was about 20 considerably, the exposure was about 20

Given an interesting figure, several variations are possible with different lighting arrangements. This is illustrated in the figure of the costumed dancer, which is another 10 cent purchase

Simulation of a stage performance by the dancing figure was accomplished by employing twelve tiny birthday candles set up on two wooden blocks before a "stage" con--isting of a box covered with black cloth. For the background a sheet of light-toned cardboard was used. The twelve candles were lighted quickly one after the other just before the exposure was made because these tiny candles burn away rather quickly To avoid including the lights in the field of view, as well as to prevent unwanted light reaching the lens and causing possible glare, the lighted candles were shielded from the lens with a cardboard blind. The presence of so many light sources caused a multiplicity of shadows to appear in the background but because one shadow was partially merged with the succeeding one and because of the large number of light sources, no one shadow was definitely apparent. If it is desired to show such a pro-jected shadow, the best method is to use only one candle, a large one, placed to one side of the figure and at about the level of the small candles or even a bit higher, provided the flame is not included in the comera view

AGFA CAMERAS

public lecture in New York City in which he described his experiences in shooting color nictures with his Leica camera, declared that he learned the proper exposure time to give under various lighting circumstances by making a series of experimental shots over a period of time. From the re-sults he was able to arrive at what he describes as his basic exposure, namely, //6.3 at 1/60 of a second, Where a higher shutter speed is required he simply runs down the scale and opens the lens wider in proportion to the speed required to stop the action involved, using the stop f/15 and a shutter speed of 1/500 or 1/1000 of a second when necessary. Similarly, in the case of subjects that are a bit too dark for the basic exposure set up he opens his lens wider for the basic shutter speed

There is much to be said in favor of Mr. Dmitri's method and it would repay every worker to set up some similar basic exposure method whether he shoots in color ot black and white. Mr. Dmitri says that he hardly ever uses an exposure meter because his exposures have become standardized by his personal method of working. However, it must be remembered that Mr. Dmitri shoots entirely in color, using 35mm Kodachrome exclusively. Having used this over a long period of time, he has become thoroughly familiar with the results he can expect under various circumstances For gen eral photography an exposure meter would seem to be one of the musts in the photographer's equipment; however, the worker must train himself not to rely absolutely on this guide to correct exposure, but to think for himself as well, and to interpret the readings rather than to follow them without question

One of the surest ways of acquiring the ability to make such interpretations is to shoot a number of different exposures of the same subject under the same lighting conditions and then compare the results Pick out the negative that seems to you to provide the type you want. If this was less or more than the actual meter reading, adjust your meter calculations accordingly For example, if the meter said f/8 at 1/100 and your shot at f/11 seemed to give the better negative, all you will have to do thereafter will be to take one stop smaller than the meter dictates, adjust the shutter to twice the speed indicated, or use a different Weston rating for your film

COLOR DEPARTMENT

RECOGNIZING the wide interest in color bolography as something that is here to stay and to bring greater demands for supplies and information as time goes on, Willoughby's camera store in New York City has insugarated a special department in its store manned by two color experts ready to answer questions and sell color materials and equipment. The management expects that this department will fill a real need and become one of the store's most cative serious properties.

FLOWERS IN THE PARKS

ONE of the chief reasons for the failures experienced by amateurs in shooting pictures of blossoms and flowers is due to the fact that too much of the subject is included in the view. Of course, we know it is very difficult to isolate a subject in such a manner that it is made to stand away from

the rest of the branch and still be appropriately lighted and have the sky for background. There is always some way out of the difficulty, even if it becomes necessary for someone to hold a branch in a certain position for the duration of the exposure or hold obstructing branches out of the way

"Japanese Magnolias"

of a particular subject. Lighting is very important, for a promising subject will be portant, for a promising subject will be missed completely if the lighting is unstitiable. One of the most effective methods is that of back lighting, illustrated in the accompanying picture of magnolias. Notice, too, that an effort was made to fring about a good balance in the composition by including the blud in the lower lift-hand

X-33 FINE-GRAIN

FORMULA

UNTIL recently a closely guarded laboratory secret, the formula from which the developer X-33 is made up has now been disclosed by the makers. The formula

follows:	
Water (85° to 90°)	26 ozs.
Diotol F-R	120 gra.
Monotol F-R	82 grs.
	. 2% 028.
Glycin	22 grs.
Sodium Phosphate Tribasic	. 45 grs.
Potassium Bromide, U.S.P.	. 3½ grs.
Add cold water to	32 pm

The chemicals are mixed in the order given, each thoroughly dissolved before adding the next. The solution may be used inmediately after cooling.

FOCUSING KINK

When working at fairly close range on a subject having cogaiderable depth and which must appear, sharp from front to back, difficulty will be encountered unless a certain well tried rule of fecusing under such circumstance & employed. Suppose

RAYIGRAM CORP

the front of the subject is 20 inches from the lens and the back of the subject 30 inches from the lens, namely, a depth of 10 inches in all. In order to determine the point at which the camera lens must be focused, it is necessary first to multiply the two distances, namely, 20 by 30 and the result by 2, which comes to 1200. Next, add the two numbers, 20 plus 30 equals 50, and divide this into the first result, 1200. The answer is 24. Therefore, it is necessary to focus on a point 24 inches from the lens diaphragm or 6 inches from the back of the object. Focusing on this point is done with the lens wide open and the closing down of the lens brings both front and back of obrect into sharp focus

TIME EXPOSURES AT

THE ZOO

MANY persons are discouraged from pic-ture-making in 200 interiors because of the poor lighting available. However, if one watches his chances he will frequently be rewarded with opportunities such as that encountered by this department in the alligator subject here illustrated. The alligators were as still as though carved in stone and a full, unobstructed view was afforded by the large window behind which they were en-

"Alligator Siesta"

joying their afternoon siesta. Because there was such a large shadow area, a relatively long exposure was required, especially in view of the stop f/8 that was required to bring the several subjects into sharp focus. An exposure of 20 seconds was made possible without the use of a tripod by resting the miniature reflex on a ledge and slightly tilting the camera by tucking the front of the eveready case under the camera.

KALART CONTEST

TWENTY-FIVE awards of \$10 each are offered in a photographic contest sponsored by the Kalart Company, who will pay the total of \$250 for the best pictures taken with a Kalart Micromatic Speed Flash. Clos-ing date is December 1, 1939, and there are no restrictions as to type of flash pictures, time when taken, and so on. Print sizes should range from 2½ by 3½ inches to not larger than 11 by 14 inches. Enlargements and contact prints are both acceptable. Nega

_and you're photographing in color

N SPITE of its modest price, this Kodak Bantam f.5.6 gives you Kodachrome (full-color) transparencies that you'll marvel at . . because they're so beautiful and lifelike, and because they're as easy to make as regular snapshots.

And just wait until you project your Kodachrome transparencies on the screen-that is something!

All three Bantams listed below have fast lenses, fine shutters, upto-date features-and all can be counted on for excellent results in Kodachrome full color as well as in black-and-white. Kodak Bantam Special, pride of the "Bantam Family," is one of the handsomest and most capable of all miniatures.

Kodak Bantams are just palm size. But when you use them for regular black-and-white pictures, modern photofinishing methods give you big prints (23/"x4"). For black-and-white pictures only, the "Family" also includes an f.6.3 model at \$8.50 and an f.8 model at \$3.95. At your dealer's . . . East-man Kodak Co., Rochester, N. Y.

What a whale of a difference a GREEN LIFA FILTER Makes ... use the correct filter with the right emulsion!

Present-day panchromatic emulsions are slightly over-sensitive for the red end of the spectrum. And, since panchromatic emulsions are popular, it is important that you use the right type of filter when taking scenes in which red, yellow and blue predominate.

You can, of course, use a yellow filter. However, in order to obtain full correction, a Green Lifa Filter is a "must". This green filter not only holds back the blue light, but also corrects fully for the yellow and red.

Let us give you a visual explanation. Here are two photographs of a still life ... showing a blue bowl, red apples and yellow bananas. The first picture, taken with a yellow filter, is sharp, but the red tone is only half-heartedly rendered ...

The second picture, taken with a Green Lifa Filter, shows a sharp delineation between the yellow and the red. Correct monochrome valuation is achieved with satisfactory contrast. You, too, can get perfect results, working indoors or outdoors, with Green Lifa Filters. Try them!

HENRY HERBERT

JUST ONE

THE LERCA-MOTOR is but one of Leica's over 500 accessories. Attach it to the Leua and you have a completely automatic camera. Up to twelve consecutive exposures can be made automatically, at the rate of two per second, by merely pressing a lever, It also permits single exposure, the shutter is wound and the film transported—automatically.

To own a Leica means release from limitations in photography, Leica is a product of the Leitz Microscope Works and is bult within the same optical and mechanical tolerances of a microscope. You are assured of continued exacting performance.

E. LEITZ, INC.

MINI-

THE NEW UNIVERSAL

The MINI is direct reading. It is present to film and shutter speed. Very small and light—measuring but 1½ x 2½ x ½ inches and weighs but 3½ ounces. Does not need a separate carrying case. Film speeds to 38° Sch. And the price is only

JACOB DESCHIN, conductor of our "Camera Angles" department, will answer in these columns questions of general interest to amateur photographers If an answer is desired by mail, enclose a stamped, addressed envelope. Queries should be specific, but Mr. Deschin cannot undertake to draw comparisons between manufactured products nor to advise on the nurchase of equipment or materials. - The Edstor

O. I am in the market for a 35mm ra and would like your unbiased opinion on the following: I have narrowed the field down to include three cameras, two with Compur shutters to 1/500 of a second and the third with focal plane shutter speeds to 1/1250. The first two are equipped, respectively, with an f/2 and an f/2.9 lens, and the last with f/2.8 lens. All have coupled range finders. I would like to take pictures under adverse conditions, including indoor and night shots. I would appreciate your comparison of the three cameras, including the following: Shots possible with f/2.9 lens and its limitations, quality of lenses, advantages or disadvantages of the two kinds of shutters, whether 1/1250 of a second can be used with an //2.8 opening. I would also appreciate the names of better quality cameras in the same price class and also the names of enlargers. S. J. S.

A. It would need a Solomon greater than he of the Bible to tell a man what camera he should buy, so many are the variables and so much depending on the individual's requirements and his personal taste li seems to us that probably the best adviser on this score is the local photographic dealer lianally he has no axe to grind, he sells all kinds of cameras and he would just as soon sell you the one as the other Let him give you the benefit of his experience, based on his contact with the many persons to whom he has sold cameras in the past. The three cameras you mention all have their good points and all will make good pictures once you learn how to use them.

Pictures under adverse lighting conditions may be taken with any lens provided you allow enough exposure Even moderate snapshots can be made in poor light if this light is sufficiently close to the subject and your film is of the "super" type. Under certain "adverse" lighting conditions, even a lens of f/1.5 speed will be madequate.

On the question of lens choice, see our reply to J.G.B., June issue; the 1/2 you refer to may possibly have a little "edge" on the others. If very high shutter speeds are what you want, you will find the focal plane shutter preferable on this account.

Many prefer the Compur because it has a tradition of reliability Nevertheless, some of the highest priced and most efficient instruments on the market today have focal plane shutters and are none the worse for being so equipped. The use of very high shutter speeds is entirely a matter of the amount of light available for photography and the sensitivity of the film emulsion in your camera. Therefore, a 1/1250 exposure at 1,28 or even smaller stop is entirely pos sible; generally, the necessary light volume will be available only when shooting outdoors on a bright day,

As to your last request, you may find the answer by making a tour of the photographic shops or by writing to the manufacturers and dealers whose advertisements appear in these columns

Q. 1 .- I have read statements of certain professionals who mentioned that they had bought a Contax and had it thoroughly checked by Carl Zeiss before they went to work with it. Does this mean that some lenses of the Sonnar f/2, 5cm specifications, for instance, are capable of better results because of the greater accuracy in manufacture? If so, will Carl Zeiss check any purchaser's camera, so that he may feel confident that, from the equipment standpoint, Toni Frissell has no better chance of join prissen has no bever canne or getting a sharper negative than himself? 2.—Is there any possible way of obtaining a sharper projected image for enlarging than using my Sonnar f/2, 5cm lens in the Magniphot enlarger? Is there meant to be any adjustment on the light source in this enlarger, or is it fixed? Have you ever seen a direct enlargement made from any 35mm negative to the tremendous size of Toni Frissell's exhibit prints? Even considering intermediate negatives, how is it possible to preserve such hair-line de-tail? And where did the grain go? 4.— Who makes the enlargements for the Zeiss and Leica exhibits?—H. W. E. 4. 1.—Carl Zeiss or any other company

will gladly check the accuracy of a camera lens for the mere asking. The reason a purchaser desires a check-up is due to the natural feeling that a camera handled on a store counter, perhaps dozens of times before the actual purchaser came along, may have been slightly mishandled by inexperienced hands. A professional photographer must be sure of results from the start, particularly if h about to undertake an important assign ment. Even if he wishes merely to try it out for a while before actually getting to work with it, he wants to be certain that he is starting off on the right foot and that if there is something wrong with the results, it is probably due to his unfamiliarity with the workings of his camera. Provided you operate the camera properly, your negat will be just as sharp as those made by Toni Frissell or any other experienced professional worker The lens that you get with your camera is not a whit better or worse than a similar one furnished to Toni Friedl.

2—The sharpness of the projected image is governed by the precision with which you focus the image on the easel and your Sonnar will give you this sharp image if you focus carefully and accurately. The light source is adjustable as to distance from the negative holder.

3 — We have seen prints of this are and even much greater made from a snaple stand the lack of while gran are due entirely to good processing throughout, from the development of the negative to the final printing. We have it on the world of the Zers people that the Frasell enlargements were made directly from the 35mm negative and that intermediate negatives were not used. In fact, they add, direct enlargement is one of the chief contributing factors to that preservation of detail and tone gradation which you admired.

4—The calargements for both the Lexts and the Zeas exhibitions are made by the individual photographers themselves. The possible exception is in the case of duplicate prints for traveling exhibitions or when the company has accumed a negative as the result of a competition or otherwise. The large marils are naturally made by an outside worker does not have the facilities for turning out prints of this size.

Q. I have a Rolleicord //3.5 and would appreciate advice as to what lens opening and distance to set for fixed focus exposures.—W. L. P.

A. If you will set the distance at 10 meters and close down the lens disphragm to 1/11, everything will be in focus from five meters —that is a little over 16 feet—to infinity. The stop f/16 will give you a still deeper field of focus, namely, a little under 12 feet as the closest distance when the meter scale is set at about seven meters.

Q. I recently constructed a small print dryer similar to commercial dryers, topped with a curved chromiam plate and covered with a removable place of canvas. Heat is supplied by two 100-wat tolectric lights in the interior. The dryer works well when ferrotyping glossy prints, but causes matter typing glossy prints, but causes matter to wrinkle all around the edges. It is there any way that this viralking can be remedical? The first batch of prints, by the way, assually does not wrinkle, but the failure of the december of the contraction of the contraction of the contraction of the contraction of the con-

A. Application of too much heat is probably the reason for the wrinkling of the

edges of the matte prints. Since the first batch of prints does not wrinkle, it is suggested that you attempt to determine the approximate temperature at which the first batch was dried and try to maintain this heat, as nearly as possible, for the succeeding batches.

Q. 1s there any difference in performance, other factors being equal, between-dilters of the stained opticalglass typs and the gelatin-cemented-inglass type? Cemented gelatin light filters are frequently described as being available in A glass or in B glass. Just what is the difference between A glass what is the difference between A glass is the importance of blu difference in general photography?—J. A.

A. So far as performance as concerned. there is practically no difference between the stained optical-glass type and gelatinbetween-glass types of filters, The principal difference lies in the fact that inasmuch as in the one case we have a solid, colored disk of glass, and in the other we have a piece of soft gelatin between two protecting cover glasses, the latter is obviously su ceptible to certain hazards from which the other is free, Among these hazards one must include the facts that the latter may not be exposed to the sun for too long a period, must not suffer too great pressure, and must generally be given greater care than the solid glass type The A glass consists of so-called "optical flats." of the highest quality but too costly for general photographic use. The B glass filters are the most generally used and are satisfactory for regular photographic purposes.

Q. Will you please give me what information you have on the subject of conventional camreas? I am informed that used an adapter, when properly adjusted upon the ordinary camera, with back removed, yields quite satisfactory enlargements. The camera lens, of course, serves to expand the image and, for this reason, the the cost of the device is relatively low in comparison to the prevailing prices of regular enlargera.—G. W, Jr.

A. There are available such enlarging at tachnesis, permitting the owner of a camera equipped with a reflevable back, to convert his camera, amo an enlarging outfit by attaching the enlarger lossing unit and negative holder. The projection of the image is usually horaontal instead of the popular vertical arrangement employed with regular enlargers. The cost of such a unit is considerably lower than that of a regular enlarging outfit, but it is significant that these units are not especially popular, workers generally preferring the complete outfit rather than an adapter.

Q. I would like to learn how to develop my own pictures. Could you give me a list of what I would need and directions?—J. N.

4. A number of developing kits are available containing the necessary equipment and supplies for developing regatives and making prints from them. These kits also include a short explanation of the photographic process and directions for developing and printing. In addition, it is suggested that you obtain a copy of an inexpensive elementary handbook, which your dealer can supply for 25 or 55 cents.

BURLEIGH BROOKS

Our Book Corner

THE Book Department of Scicutific American is conducted, with the ecooperation of the Editors, to make available for you a comprehensive book service. Each month the Editors select and review in three columns new books in a wide range of scientific and technical fields. In addition, they are ready at all times to adsize you regarding the best available books on any subject. You are invited to use this service freely. Tell our Book pour bear that of books you want and you will be furnished with a list of available titles, including prices. When inquiring about books, please be specific; remember that we can be of the greatest help only when you tell us just what you are looking for.

MEN, MIRRORS AND STARS

By G. Ldward Pendras

A NEW edition of a book whith many A materix relescope makers purchased four years ago when it first appeared, licause of its large content of elementary background about relescopes and of lore of professional telescope makers of the past. Chréf addition now is a chapter on the 200-unch telescope. (341 pages, 5½ b) 8 inches, 78 illustrations >= 83 to pressuit = 4.6 e.f.

WHAT SNAKE IS THAT?

By Roger Conant and William Bridges

A COMPILATION of careful description turns of the suskes of the United States, the fluenced States, and the dawning to show types of sales, head structure, and hody markungs of the sunkers of the sunke

YOU'RE THE DOCTOR

D R Heiser, author of "An American Chatty, remnscent, anecdoal book on foods and how they affect us, likewise on ways of bring, together with the whys. Absorbing reading and full of common-ense health information (300 pages, 5½ by 8 melus.) —22.60 postpaged — 4 C J.

LIFELIKE PORTRAITURE WITH YOUR CAMERA

By W. H. Doering Translated and adapted by L. A. Leigh, F.R.P.S.

A COMPREHENALY work on what is probably the most important subject type in all photography, this book takes the trader on a practical tour of all the important aspects of portrature 11 tells him what independent is be anaphoto portrain from the more exalted types 11 classifies camera, and explains their special usefulness in this field. A valuable section is that devoted to lenses, There is also helpful guidance on the subjects of selecting the proper negative material, development, terotoching, paper, com-

position and trimming, and the mounting of the funshed picture. A helpful index, many funcillustrations, and helpfuling diagrams plus good readable type make this book will worth any amateur's money (108 pages, 58 photographs and many diagrams, 6 by 8½ undex) ~ 2.01 mercipad. J D.

POISONOUS PLANTS OF THE UNITED STATES

By Walter Courad Muenscher

DIANTS causing poisining when ratin or by contact or by nechanical maps; by man and animals are tracted by name, description, distribution, and habitat, also a coulding to their poisionies principle, conditions of poisioning, symptonis, and sometimes by remed ya, in this reference host. It includes namirous full-page drawings of the planeau dictions of the planeau of their parts (206 pages, 37; by 87; miches, 75 albistrations) (1—8160 postpard).

ARC WELDING IN DISIGN, MANUFACTURE AND CONSTRUCTION

I dited by The James F. Lincoln Are

REPRESENTING a compilation of pation sponsored by The James F 1 mooln Arc Welding Foundation, this volume is amazing in several ways. Its wealth of material may be noted by its total of 1408 pages. The papers reprinted or condensed therein discuss the practical aspects of welding, the great savings effected by its use, and ingenious solutions to construction problems that have been actually encountered by the entrants in the competition Hundreds of drawings, photographs, tables of costs and specifications, and mathematic calculations are included This could become a hible for all those interested in welding (1408 pages, 6 by 9 mches, limp leatherette 1-\$1 50 in United States, \$2.00 clsewhere .- F. D. M.

YOU AND YOUR MONEY

By C. Donald Dallas

COMMUNISTS will not wish to read this volume by the President of the Revere Copper and Brass Company. The author discusses logically and, we think, more objectively than would his opponints, the question of capitalism and industry obtaining in this country today. Naturally, communism comes-

in for some straightforward criticism. Long folding graphs are included to show 100 years of conomic progress and 150 years of real-relate activity. From these the author draws important conclusions regarding our democracy (85 pages, 5½ by 8½ inches,) -\$160 noveland −F, D M.

MAHAN

By Captain W. D. Puleston, U. S. N.

THE writings of no American military man have influenced the world's military tastics so greatly as have those of Captian Mired Thayer Mahan, United States Navy. The mail academies of the world still study his looks on mail strategy, and it was three that strongly influenced the naval building arrivates of world powers before the World War. His writings were indeed carefully samed by all mail students whether they appeared in book or magazine arrivele form.

The present hiography—by a former Drece of Naval Intelligence, and, medentally, a contributing editor to Scientific American res a sympathetic and comp ling story of the life and work of this man who is too little known to the layman. It might be apily characterized by a chapter heading near the coun hosson, entitled "Mahan's Income and the contribution of the layman in the contribution of the layman in the contribution of the layman in the layman's layman's layman's layman in the layman

PRESS PHOTOGRAPHY WITH THE MINIATURE CAMERA

By Duane Featherstonhaugh

A WORKING press photographer with many years of experience in the field and no prepuderes to handreap him, tell-he anateur how he may turn his spare time into spare dollars by making pictures of the press. The book is completely practical and takes in as much of the field as will be useful to a telepiner. The book is well-like useful to the benner. The book is well-like useful to a telepiner. IT'S NICE TO KNOW PROPLE

By Harry Walker Hepner

A NOTHER of the recent spate of successful books on getting along with other people, and most interesting reading it is Objectively described, however, most of the recommended methods amount to being two-faced, using subtle flattery, saying insuncer things, and being all things to all people as the occasion seems to call for, but there is

We can supply our readers with any of the books reviewed in this department. Prices quoted include domestic postage. Foreign prices are necessarily higher due to increased shipping charges.

SCIENTIFIC AMERICAN 24 West 40th Street New York, N. Y.

overwhelming evidence that it works-what fools these mortals be. The book also contains honest advice on becoming socialized. (172 pages, 5 by 7½ inches)—\$1.60 post-

MOLDING AND CASTING

By Carl Dame Clarke

RAFTSMEN, criminologists, dentists, artists, pattern makers, and others whose vocations or avocations make desirable a broad knowledge of the materials and methods of molding and casting, will find in this book a mass of material, much of which heretofore has been carefully guarded as "trade secrets." The content covers such phases as making molds in plaster, sulfur, wax, and so on, how to use them for various purposes, and how to cast with them (308 pages, 61/4 by 91/4, 69 photographs and drawings)- \$4.60 postpaid -- A. P. P.

WEATHER

By Gayle Pickwell

AN elementary, popular treatise on weather lote, especially in the West. Not a text-book. (170 pages, 9 by 11½ inches, 59 large and beautiful illustrations of clouds and other phenomena) - \$3 10 postpaid - A.G.L.

PROTECTIVE COATINGS FOR METALS

By R. M. Burns and A. F. Schuh

DESIGNED for those who have problems of protection, this volume is not a manual for the production of protective coatings. It is an exhaustive work covering the evaluation, application, and methods of testing of metallic coatings, paints, and miscellaneous coatings. The mechanism of corrosion and surface preparation are also discussed in relation to protective coatings. An American Chemical Society Monograph, well illustrated and indexed (407 pages, 6 by 9 inches)—\$6.60 postpaid—L. B. P.

FROM HEAD TO FOOT

By Armitage Whitman, M D

AN orthopedic surgeon of long experience, consultant at the New York Hospital for the Ruptured and Crippled, sets down m clear, readable, understandable form just the background of information, chapter by chapter, about cases involving the foot, howlegs and knock-knees, curvature of the spine, congenital deformities, infantile and spastic paralysis, fractures, osteomyelitis, joint in-juries, tuberculosis of the bones and joints, low back pains, physiotherapy, operations, which he might explain orally to a layman client or client's parent of obvious intelligence in the course of an hour's serious consultation (262 pages, 51/2 by 8 inches.) -\$2.60 postpaid .- A. G. I.

FORGING PRACTICE

By Carl G. Johnson

PRACTICAL treature on hand forging A of wrought iron, machine steel, and tool steel; drop forging; and heat treatment of steel, including annealing, hardening, and tempering. (136 pages, 5½ by 8½ inches, 121 illustrations.) -\$1.60, postpaid. - A. G. I.

TELESCOPTICS

A Monthly Department for the Amateur Telescope Maker Conducted by ALBERT G. INGALLS

PEW refracting telescopes are made by amateurs—perhaps because of the time and accessories needed, but largely, it is suspected, because in earlier years when amateurs regarded optical work with award mystery a tradition that objective lemmaking was very advanced work became established and has not yet been scotched Yet, whenever someone who has made one

Figure 1: Garrison and refractor

writes to this magazine, he never mentions any especial history of trials, tribulations, and headaches. The job, with its four surfaces to work, is a hit tedous, and probably should not form the beginner's madern optical work, but for all its tedhum it is optical work, but for all its tedhum it is not more difficult than reflector making not more difficult than reflector making years may who dared not tackle a refractor convened themselves, because of this reflect, that the reflector was upgered. But most persons who are honest with themselves and who know both instruments do

not say this Each type has its superiorities, one superiority for the refractor being much steader images

In Figure 1 is an 8" refractor made by H. P. Garrison, R.F.D. 1, Oceanside, Calif, working from the very detailed instructions by Haviland in "ATMA", the companion volume to "Amateur Telescope Making"

"The objective lens," Garrison writes, "was made from a part of Chance Brothers hard ctown and dense flint, ground to a focal length of 184", or 1/16/75.1 spent much time regranding and polsching five times, but 1 did not mind that because twas learning all the time. Now I have a lens that will stand 75 diameters' magnification to the aparture inch when the seeing is good, and I feel! an were well repeal for the extra

"The mounting is made from Chevrolet truck perts, steel pipe, and boiler plate, and the axes are mounted on ball bearings. The tube is of 20-gage galvanized iron 8½" in diameter.

"The mounting works very smoothly but, in the wind, as shown in the illustration, taken before a 14' by 14' roofless observatory with 6' walls was creeted, it was very shake."

"The cell, Figure 2, is made of aluminum cast in one piece, and is held in place by means of brass clips. This permits removal of the lens without disturbing the adjustment."

PRAMED attractively in the twigs of a fengiboring tree, as shown in Figure 3, stands the huge, 137 done for the 200° telescope, atop Mt Palomar, California, with the great mounting inside practically ready to receive the big mirror next year This artistic photograph was taken by Ted Watterson, official photographer at Mt Palomar

Figure 4 is a 1/340-scale replica of the same great dome, cast in brass and aluminum by Fred Ferson, 404 Reynoir St., Bilox, Mass, author of the chapter on molding and casting in "ATMA". The patterns were made by Russell W Potter and presented to Ferson, a friend, Ferson then poured the castings, mechanical them, and makes of the replica in not intractive adult of the property of the presence of the present of the presence of the pres

The base is 8½" in diameter, is made of brass, weight about six pounds and is let 'tred' Two-hundred Inch Telescope Observatory A D. 1940. This brass base includes an integral standing collar part reaching upward as far as the bead seen above the entrance doorway. The upper portion is cast

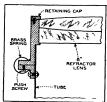

Figure 2. The clip-attached cell

in alumnum, contrasting attractively in hue with the brass base, and consists of a hollow spherical dome 59%." In diameter, to which an accurate replica of the shutters is attached facely. This upper portion may be rotated, as on the original, also lifted off to get at the interior, which is machine-finished.

Figure 3 · Big dome at Mt. Palomar

Figure 4: Ferson's big-dome replica

Sharp-eyed comparisons will reveal that the entrance door in Figure 2 differs from that in Figure 1, the original. These, how-ever, are different doors and on different sides, the door in the replica being the huge one for the introduction of the big mirror and the other merely for the introduction of the astronomers

In Figure 5 are two lesser items cast by casting-enthusiast Ferson. The larger is a

Figure 5: "Mirror Maker" and "Nut"

34 ounce brass plaque, 5" by %", made from a pattern by Porter who, when visiting at Ferson's home, poured plaster of Paris into a metal ring and with his jack-knife quickly whittled in bas relief in the soft plaster the cartoon of the "Mirror Maker" and straining at his work of preliminary polishing. The smaller piece (32 ounces) is a brass "Telescope Nut" peering into an eyepiece from an awkward seated position, and was cast by Ferson from a pine pattern whittled out by Porter. The two photo-graphs on page 337 of "ATMA" show Feron with Porter smiling at the camera.

STELLAFANE'S annual convention or informal get-together of amateur telescope makers and astronomers will be held atop Mt. Porter, near Springfield, southeastern Vermont, on Saturday, July 22. All having interest in astronomy or telescopes may come freely and bring families, friends. They will find about 200 others similarly afflicted (that is, telescopius, families) sitting on grass or hard outcrops of Vermont lurassic schists ready to swap chin-music about telescoptics from noon to six. Then comes supper en masse in a big circus tent (about a dollar). At dusk, reports and speeches by amateurs from hither and you begin and wear on till all are unconscious. following which those who revive may stay all night, using Stellafane's telescopes and those brought by visitors—bring yours. Good parking Places to camp. Bubbling spring. Scenery. Air. Not a mosquito.

IN February 1938, in these pages Clyde Tombaugh of Lowell Observatory, described his sun telescope: a 12" mirror, unsilvered, a right-angled prism with diagonal face turned directly toward the mirror, thus diverting some 93 percent of the light away the other faces, and a pair of smoked glasses worn by the observer-the overall reduction in these three cutting the solar light to 1/7500 strength and thus permitting comfortable study of the solar surface. In April of the same year D. Everett Taylor told how to make a Herschel wedge of the general kind described by Bell, in "The Telescope," for use on Sun, Moon, and Venus, this being an attachment between telescope and eyepiece designed to divert or throw away 95 percent of the light by means of a thin, wedge-shaped elliptical

8 or 10 degree, plate glass prism. Alan Gee, "ATMA" p 320, a cadet at the United "States Military Academy, West Point, N.Y. in rummaging round the previously innied but recently rehabilitated observatory there, ran across the item shown in Figure 6, an old polarizing diagonal of considerable value, and at our invitation hidescribes it as follows.

"A diagonal employing the principle of polarization by reflection to cut the bins a light and heat down to a minimum without cutting the aperture (see Bell, "The Telescope", pp. 167-8) gives beautiful colorless views of the Sun The following is a descrip-

Figure 6: The polarizing diagonal

ROM TELESCOPE
Figure 7: A longitudinal section

tion of such a diagonal (probably made by Alvan (lark about 1880) as used on a 12" refractor of 180" focal length at full aper-

"The construction of this diagonal is very ample. It consists essentially of three wedge (Herschel) prisms, two of which are so mounted that the incident and reflected rays to each make angles of about 57 degrees with the normal to the reflecting sur faces and thus are plane-polarized. The third wedge is intended to increase the available light range and to get a favorable observing position, and is mounted just in front of the eyepiece like an ordinary diagonal. Figure 7 shows the arrangement schematically, and Figure 8 as it appears in use. The tubes of the diagonal are of brass, soldered at the necessary angle. The two separate parts of the diagonal—the lower part A, (Figure 7) carrying one prism and attaching to the scope, and the upper part C carrying two prisms and the eyepiece—rotate with respect to each other about the short connecting tube B. This rotates the planes of polariza-

Figure 8: Diagonal on 12" refractor

passed on to the eyepiece and eye "For minimum light," Gee continues, "tube C would be perpendicular to tube A, as shown in Figure 6; for maximum light they would be parallel, as shown in Figure 7.

"The wedge prisms in this particular diagonal are mounted against soldered shoulders in separate pieces of tubing that slide into the soldered tubes forming the angle. This simplifies construction and allows removal for cleaning.

"The angle the wedges must make with the incident ray is a function of the index of refraction of the glass used. The equation, tangent $\theta = \mu$, where θ =the angle between incident ray and normal, and $\mu=$

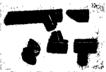

Figure 9: The diagonal dissected

index of refraction, gives the exact value of the angle. For ordinary glass (µ=1.55, approx.) the angle is 57°. As all the mcident rays are not parallel, anyway, thus is close enough for most conditions. However, if a particularly light or dense glass is used, the exact angle should be calculated.

"Silvered surfaces or the like will not polarize by reflection, although colored glass will Black glass can be used in place of wedge prisms if available, but should be used with the third wedge of clear glass to discard extra heat. The new polarizing materials now on the market, usually consisting of thin sheets that polarize by transmission, are not suitable for a diagonal. They pass the violet and deep red (and most of the heat) even when set for ex tinction, and thus are but little superior to any colored filter. Nicol prisms will work if available but are far too expensive.

"The biggest advantage of this type of diagonal lies in the fact that it cuts down the light (and heat) without cutting the aperture and without coloring the image. No colored glasses are needed. The Sun appears perfectly white and can be rigidly controlled in brilliance simply by rotating one tube with respect to the other. The difficulties of construction should not be great, the optical surfaces representing most of the work. If used on a reflector one of the wedges mounted at the required angle could well replace the main diagonal, the other being mounted before the eyepiece. The beautiful views that such a set-up gives of the 'rice grains', spots, and faculae on the Sun surely make it worth considering."

TRADE MARKS AND UNFAIR COMPETITION

By ORSON D. MUNN

A Trade Mark is an intangible asset of a business, yet its actual value may grow so large that it becomes the very foundation on which depends the whole structure of the business Because of this fact, every business man should have available such information on trade marks as will enable him to judge with a fair degree of accuracy the desirability of any mark which he may be considering.

Here, in one handy volume, written in non-legal terms, is a simple yet comprehensive interpretation of the Federal statutes and the body of common law relating to trade marks and unfair competition.

Patent, Trade Mark, and Related Legal Proceedings That May Have a Direct Effect on Your Business

By ORSON D. MUNN, Litt.B., LL.B., Sc.D.

New York Bar Editor, Scientific American

RETURN MATCH

THE maxim "If at first you don't succeed, ity, iry again" does not apply to patent language. It, in a sout filed by a patentive against the manufacture of smaller and another than the state of the smaller and in the state of the smaller and the state of the smaller than the state of the smaller than the state of the smaller than the state of the state of

This principle was recognized by the United States Supreme Court many years ago in a suit in which an injunction was tranted against a patenter restraining him from sung the customer of a manufacturer after it had already been determined in a prior suit that the manufacturer did not infringe the patent in question.

More recently the principle was reiterated by the Circuit Court of Appeals for the Fourth Circuit in a suit in which the Court held that a patientee was estopped from charging that the customers of a manufacturer were infringing the patient in suit when it had been determined in a prior suit against the manufacturer that the article produced and sold by the manufacturer did not intered the court states.

"In such case we think that the patentee is estopped by the judgment in favor of the manufacturer from recovering damages on account of infringement from persons who have purchased from the manufacturer the articles which are alleged to infringe but which in the judgment have been held not to infringe."

FOREIGN INVENTION

WHERE a patent is obtained in the United States by a non-resident who developed the invention abroad, the question frequently arises as to the date of invention to which the non-resident inventor is entitled. In other words, under our patent law, is the non-resident inventor entitled to the date on which he conceived, developed and reduced the invention to practice abroad, or is he limited to the date on which he first introduced the invention into the United States? Arbitrary and illogical as it may seem, it nevertheless is a fact that, if the question arises in a proceeding between the non-resident inventor and an infringer owning a patent or a patent application covering the same invention, the non-resident is only entitled to prove the date on which he first introduced the invention into the United States, whereas, on the other hand, if the question should arise in a suit brought by the non-resident against a person who

does not own a United States patent or patent application, the non-resident is entitled to prove his date of conception and reduction to practice abroad.

This is illustrated by a decision of the United States Supreme Court in a suit for patent infringement brought by a resident and citizen of Japan against an American company. One of the patents in suit was applied for in the United States in January, 1922. It was proved by the American com pany that it had used the invention covered by the patent in commercial operations since June, 1921, almost a year prior to the filing of the patent application. However, the American company did not obtain a patent on the invention. It was held that under those circumstances the Japanese was permitted to prove that he had conceived and reduced the invention to practice in Japan in 1919 which was prior to the commercial

use by the American company The Court pointed out that if the American company had obtained a patent in the United States the Japanese would have been precluded, under the American patent law, from proving his dates of conception and reduction to practice in Japan and would have been limited to the filing date in the United States as his date of invention. Under those circumstances, the patent would have been invalid because of Lnowledge and use in the United States prior to the proved date of invention by the Japanese. This rather arbitrary distinction as to the rights of a non-resident inventor against an American patentee on the one hand and against an American who does not own a patent on the other hand places a penalty on an American who does not obtain a natent on an invention. The Supreme Court recognized the arbitrary character of this distinction but said that it could only be corrected by legislative action since the courts were bound by the patent law as enacted by Congress

In this connection the Court started:

"We have no way of knowing whether the discrimination results from inadvertence or from some undisclosed legislative policy, but, in order to redress the disadvantage under which one in the petitioner's situation suffers, we should have to read into the law words which plainly are missing. We cannot thus rewrite the statute."

VINYL RESIN

WHEN does the substitution of one tion? Ordinarily the substitution of one material having known characteristics for another material having similar charactersities does not amount to invention expenthough improved results might be obtained. However, where the substitution of one material for another produces a new and unexpected result or where it solves a problem of long standing in the art it to held that the substitution constitutes inven-

The principles of law set forth above are relatively simple but the application of the principles to any particular set of facts is quite difficult. The difficulty presented in such cases is illustrated by a recent suit brought against the Commissioner of Patents to compel him to issue a patent for an improved package or container. The package consisted of a metal container having a coating or lining formed of vinyl resin for the purpose of protecting food products packed therein Other coatings or lining materials had been used on metal containers and it was argued by the Commissioner of Patents that the substitution of the vinvl resin coating for other types of coatings constituted a mere substitution of materials and did not amount to invention.

The Court found, however, that for many years it had been recognized that it was desirable to coat metal containers for food products with some type of material that would protect the food product from the action of the metal However, no satisfactory coating material had been developed for metal foil used in packing cheese or for metal containers for beverages. The Court found further that the use of a vinyl resin coating material for these purposes solved the problems of the prior art and provided a satisfactory package that could be used with all types of food products. The fact that the substitution of one material for another resulted in solving a problem of long standing in the art was considered by the Court to be proof of the fact that the development of the package constituted in vention and warranted the granting of a patent.

PERSONAL PERFORMANCE

A MUSICIAN or other interpretive artist may control the use to which electrical transcriptions of his renditions may be applied. This is illustrated by a suit brought by an orchestra leader against the proprietor of a radio station to restrain the unauthorized broadcasting of electrical transcriptions of renditions by the leader's orchestra.

The orchestra had made certain electrical recordings to be used on a specific radio program and the records contained a notice that they were to be used for that purpose only. The proprietor of the radio station used the recordings in connection with an unauthorized use program and the leader of the orchestra filed suit to restrain such unauthorized use.

The Court granted an injunction, holding that the renditions and interpretations of musicians were property and that the musicians had the right to restrict the use thereof. In its opinion, the Court stated:

"The great singers and actors of this day give something to the composition that in particularly theirs, and to say that they could not limit its use is to deepy them the right to distribute their art, as they may see fit, when they see fit, Sureth, their labors or and and talents are entitled to the privilege of distribution, especially where, as here, the privilege is subject to definite terms and

126

BY means of the method described on page 34 of this issue, for drilling oil wells at controlled angles from the vertical, it has been found possible not only to obtain more oil from underground sources but also to extinguish raging oil well fires and to bring "wild" oil wells under control. The secret of the process hes in the ability to direct and change the angle at which drilling proceeds.

SCIENTIFIC AMERICAN. August, 1939 Vol. No. 183, No. 2, entered at the New York, N. Y., Past Office as second class matter June 28, 1279 under the act of March 200, 1379, additional entry by the Company, it was to the Company in the

50 Years Ago in . . .

(Condensed From Issues of August, 1889)

ELECTRICUTION—"A murderer in New York named Kemmler has been sentenced to death, and his execution will be the first under the newly enacted law by which electricity is substituted for the rone hanging being abolished."

EXPOSITION.—"Visitors to the Parts Exposition take great place auer in being cartred from one end of the Machinery Palare to the other on the electric rolling bridges, a general view of which is given in our engraving. In fact, they are not indifferent, when on foot or on this original vehicle, to traversing the 1300 feet of the colosial gallery in which are accumulated so many wonder-

of mechanics. Moreover, many of the visitors, if not all of them, overgreene an intelligent sustaination in thinking that the missing lower necessary for this aerial trip is furnished by electricity, and constitutes an interesting example of the transmission feet trical energy to a distance—that problem which is now in a large measure solved.

ICE WATER—'In the symmon of the editor of the Santary Lodanter. It here is a great field of sentiment and many opinions regarding the use of see water that vanish when the light of reason and experience is turned upon them. The fact is that see water, drunk showly and in moderate quantities, constitutes a healthful and invigorating drink. It measumpton that toed water is diagrenus, and that teed to are reasonable to the samples of the second of the samples of the second of

DIAMONDS—"The practical production of the diamond by artificial means has been the theme of a great deal of thought and a good many experiments, but up to this time it has eluded all the efforts of the experimenters, though carbon crystals closely approaching the gem have more than once been secured, while many persons still think it is merely a matter of time, and not a long one at that, when the secret will have been wrenched from nature."

PATENTS—"The Supreme Court has repeatedly said that a man's right under his patent for an invention is as absolute as under a patent for lands, and no one would say that one should lose the right to his house because some one else saw fit to take possession of it against his will."

FLICHT.—'When human ingenuity can match the product of nature, when it can make a marhine possessing as much power and indirance to the ounce of weakli as that of the boning pigeon which lately flew from Detroi to Buffalo (225 mires) in less than four hours, when it can so arrange and automatically shift a series of vances like shifting feathers in a hawk's wings, which suspend it in the art for hours almost without apparent motion, when it can

solve the problem of how this same hawk drops like a bullet from the dizzing height of a half mile, and check- itself unharmed above its prev, then it may learn to travel in the air."

BORAX—"New horax works have recently been started in Salmsvalley, Inyo county, California They have cighteen crystallizing tanks, each of a capacity of 1000 gallons. Three of these tanks are emitted daily, yielding about two tons of borax."

TRANS-SIBERIA—"The proposed Siberian railway is to extend from St Petersburg to Vladivostock on the Pacific Ocean, which is located nearly opposits San Francisco, and distant therefrom about 1000 miles Branch lims of the proposed road would extend to Pekin The new road would be about 4500 miles in length.

ELECTRICITY—"There are now in use in the United States more, than 56.0 central electric stations for light and power There are 210,000 are lights and 2,600,000 incandescent lamps. There were fifty-muc electrical railways in operation in March last, electrical railways in operation in March last, and eighth six roads in process of construction. The micrase of capital in electrical minestiments during 1888 was nearly 870,000,000."

WARSHPS—"On August 22, proposals are to be opened at the Nay Department for five new removes, to be built on plans copied from what are now obsolete English ships, slow in speed, lacking in offensive and defensive means, not the latest and hest designs. It is to be hoped the Secretary of the Nay will be able to design the ward of construction until Congress meets and time is given to modify the proposals so as to substitute later and hetert designs."

CIGARETTES—"Observation in public places gave satisfactory condence that the use of cigarettes is rapully on the decline. Whether this is due to the strangent laws passed in many of the states against selling them to minors, or that smokers have come to their senses and have taken warning from their own expensee and the unaminous condemnation of smoking cigarettes by the medical profession, or whether the evil practice has begun to be looked upon as a discreditable were to be only practiced in secret, we know not, but it is certain that, as compared with the past, very few cigarettes are now smoked in public."

PHOTOGRAPHY—"Modern amateur photography . . . consists, substantially, in pointing a camera and touching a spring. It requires no study, no knowledge, no experience, no genus, no skill. Even children are now photographers, and the camera is coming to be a toy."

 The Bell System cordially invites you to visit its exhibits at the New York World's Fair and the Golden Gate International Exposition, San Francisco.

OUR POINT OF VIEW

Upward

WHILE a fear-ridden world is talking of nothing but war, it is truly refreshing to hear another note sounded—one that includes the word "armaneni" but with a meaning far removed from warfare. From England, the Scandinacian countries, the King of Begium, the Queen of Holland, and now from the President of our own country has come a call—a call to arms. But what a different call, for this is a call for more of rearms—call, or the is a call for the second rearms—

These far-seeing people realize, as everyone must, that unless something is done disaster will overtake the nations of the world as it has in the past. We must not forget that nations are aggregates of individual beings, and until man changes himself we cannot expect nations to be very different. Aesop long ago, in the fable of the human body, pointed out a great lesson-that every one of us is dependent upon each other. When the individual himself will put into practice the fundamental principles of unselfishness and honesty, we will find in our business life and in our national life a great change; and as the individual and the nation change the international peace of the world will be assured. We will have both national and international peace and prosperity .- A. M. T.

Commerce

GOME months have passed since the Jiner Paris, burned at her pier, Yet that disaster still may serve as an object lesson to shipbulders throughout the world. Fire may strike any ship, large or small, if built by traditional designs and of the usual materials. And when it strikes, sometimes there is a ghastly toil of life, as was the case when the Morro Castle burned off the New Jersey coast several years after

As we contemplate with no little national pride the plans for upbuilding the American merchant marine (discussed by H. Gerrish Smith on other pages of this issue) a greater pride grips us at thought of all that American designers and experts have done to make all our new ships fireproof. Fires can start on practically any of them, but will burn themselves out quickly. The principle behind the use of the newer designs and the newer materials is to insulate each partition, each bulkhead, each deck, against any spread of a blaze.

The details of the fireproof features of the Ancon and the Panama, of the Panama Railroad line, were discussed briefly in the April, 1939, issue of Scientific

Albert A. Hopkins

E DITOR, author, antiquarian, bioliophile, Dickens scholar—wide were the interests; in dustrious the mind, kindly, considerate, and tolerant the actume of this man whom we called friend and our readers looked up to as mentor. Our Associate Edutor for 44 years, until his retirement three years ago, Albert A. Hopkins passed away on June 9 at his home in New York. Cuty, at the sage of 69.

Mr. Hopkins followed in the footsteps of his father who was also associated with Scientific American for many years. Editing and writing came so easy to him that he found time for many other broad interests during his busy and productive life. Fame. which might have been his for the asking, held no glamor for him, for his was that rare mentality which loves achievement for its own sake. He wrote, compiled, and edited a large number of books, at least one of which sold into the hundreds of thousands. An authority on the history of art, he collaborated with the late Edwin Howland Blashfield in editing Varsari's "Lives of the Painters." To the New York Public Library, he presented a valuable collection of 4000 mounted photographs of Italian paintings and statuary. He was one of the guiding forces in the Dickens Fellowship of New York, a former vice-president of that organization and editor of its publication, The Dickensian. He was also Director of the American Museum of Safety and editor of its official monthly publu atton.

Proponent of progress in science and the arts, and an encyequit, indefatigable worker for those ideals that make men great, Mr. Hopkins achieved a unique greatness of his own transcendent joy in the art of living. He took the utmost for living. He took the utmost for life and gave full measure in re-

We shall miss him for we were honored to call him friend.

American. The America, largest merchant vessel ever constructed in this country, will be made, in a similar manner, proof against fires. Likewise, the new construction will be featured in more than 20 combination cargo and passenger ships which are now on the stocks. These are following the lead of oil tankers built during recent years, all of which are immune to sweeping, disastrous fires

Here then, we repeat, are two sources of pride-justifiable pride-for the American people. After long years of apathy toward our merchant marine, years in which we permitted other nations to outstrip us on the seas, we have at last ceased our fumbling attempts to plan shipbuilding programs and will have a merchant fleet befitting our world position No longer may the analogy of the department store owner who delivers his orders in his competitors' delivery trucks be applied fully to us, our own bottoms will handle a much greater proportion of our export and import business than they have for many years. The second-and in some respects more important -- point is that our new ships will be the safest in the world. We have long stood with the best in general safety but have now definitely taken the lead in the development of completely fireproof ships It is to be hoped that our studies and experience may be made available to and be used by other nations so that fire at sea may some day be a thing of the past -F/D/M

Is Man Sapient?

RECENTLY, A C Chick of the Manutacturers Mutual Fire Insuitance Co., tod the Sensionological Society of America, Eastern Section, that the volume of continuals mirrance took a sudden leap continuals mirrance took as udden leap of 1925. The California premium alone reached a total of \$3,000,000, by 1928, however, the premium had fallen to \$2. 00,000 and by 1922 it was only \$750,000. Shortly afterward came the Long Beach quake ("Oh. wby did we let that insuirance lapse?"). Exactly the same crescende and diminendo followed, the totat quake premium for the whole nation today being only \$1,000,000.

Now, since the least dangerous period to soon after a great quake, when earth stresses have been satisfied, and the most risky period some years later when new ones are secumulating, it sounds as though perhaps man wasn't the alto-gether intelligent gambler implied by the term Homo sapiens. An odd sidelight on emtonatel effects of recent experiences is that the New England hurricane of 1938 stimulated earthquake insurance! This should not be let lapse. The east, too smug about the west's quakes, is largely a seismic area, as it may someday discover to its sortow.—I, G. I.

Personalities in Science

D AYTON C MILLER is Professor of plysacs at the Case School of Applied Science Cleveland, Ohn, Readers will recall him as the scientist whose mane figured so frequently in the newspapers a dozen years ago in connection with a notable experiment on their diff. However, Professor Miller's special in trests within the field of physics are far broader than ether drift and they include the velocity of light in a magnetic field the explanation of gases. Roentgen rais, applications of the interferometer, the photographic registration of sound waves, and the quality of musel sounds.

Is there actually an ether A century and a half ago students of science would have asserted with honest conviction that calone and phlogiston were actual entities having reality. Today we know these were merely words with no reality be hand them Largely it is suspected, they acquired their high prestige from common and frequent use. They were burned into the mind. Half a century ago the word other had similarly high prestige and solid standing. People took the existence of an other much for granted but it is suspected that the reason again was its common and frequent use, especially in teaching, for there never has been any really water-right, final experi mental evidence for the existence of an ether. The concept was simply a postulate. Light had to be transmitted by some medium, hence there must be a medium Logic, But logic unsupported by experi ment often leads astray in science Is ether then to turn out to be only a word like caloric and phlogiston! There is a marked human tendency to confuse names with things to name something we think exists and then to feel sure that it exists, or even that we then understand it Thus far, anyway, science does not know whether there is an other or not. Preponderance of evidence seems against it at present

In 1887 the famous Michelson-Morles, tether drift experiment had given no evadence that there was an other Subsequent repetitions in others gave puze to ally the same results. Squarely on these findings Professor Einstein based in 1905 theory of relativity. Thus, when Professor Miller came to repeat the 1904 theory of relativity. Thus, when Professor Miller came to repeat in 1921, 1924-20, and in 1929, it took on greatly inchanced weight and the public heard much about it through the press. After very many & acceedingly laborious indi-

DAYTON C. MILLER

vidual measurements he came to the behef that he had isolated evidence of an ether drift, therefore of an ether

Scientists the world over awarded Professor Miller's research very close, serious attention, especially because they knew his record and personality and approved of both. The former was that of a careful, level-headed research worker who habitually kept emotional factors out of his mental processes --major part of the method of science itself. The latter was (and still is) genial, calm, quiet, simple, unpretentious, and unaltered by the award of medals and honors. Scien tists knew he was not seeking merely to prove" the existence of an ether or out to "get" relativity approaches which would be motivated and therefore contrary to the method of science-but was making an experiment and observing the results. To this day these results have never been satisfactorily explained away Professor Miller does not root vehement ly for them as some might. He says calmly that the details of his work are now in the record, and that the future will prove them true or prove them wrong In this he resembles Professor Einstein who, when told of Professor Miller's findings, calmly said that if they were finally serified the theory of relativity would automatically disappear. That is science

A wide sector in Professor Miller's scientific territory has had to do with sound and music and readers will recall his book, published two years ago entitled. Sound Ways, Their Shape and Speed," a work for the popular reader

But he is also a musician as well as a misse lover. Skill as a flute player, he used that instrument first in his researches on sound He owns a collection of flutes of all varieties, numbering no less than 1300. Chuives jate flutes, walkingsick flutes, a glass flute one owned by President Madson a human slamon flute, affut made from the wing of air eagle, an East Indian nasal flute, and many other odd flutes, also 35 modern flutes. But he is no mere collector, he can play these flutes and doors.

Professor Miller's most recent book is an illustrated, popular, anecdotal history of electricity named "Sparks, Lightning, Cosmic Rays"

DELICATE BLADES IN A LINER'S POWER PLANT

HIGHLY skilled mechanics are needed for the intreast job of blading the low-pressure turbines that will be a part of the driving machinery of the great lines America, now being built as part of the program for a finer merchant marine which is discussed on page 88 of this issue. Some 15,000 of the delicate blades will be required—arranged in circular parallel rows—in the shell, or casing, of this turbine. The photograph shows half the casing with semicircular rows of reaction blades in place. Another 15,000 blades, similar to these but called impulse blades, will be fitted to the rotor which is to be mounted in this casing. The projecting rows of impulse blades on the rotor will dovetail into the spaces between reaction blade rows of the closed casing, between reaction blade rows of the closed casing.

To man, a building is such a familiar thing that he seldom pauses to think that its strength from sidewise directions is far below its vertical strength (against gravity). In non-seismic regions this is adequate, but in earthquake areas horizontal forces about half as strong as gravity may occur. The best answer is to provide a much heavier system of diagonal braces. This requires altering human habit, custom, tradition—a slow process

Plute by Ben S Beer

Earthquakes Need Not Kill

THERE was no warning, only a deep and terrible roar, and in four seconds the town of Pegu in Burmese India lay in runs, destroyed by an earthquake. Before the frightened inhabitants could run a single step their flimsy city had buried them.

The earthquake is the swiftest and most ggants unanfestation of power ever seen on the globe. It dwarfs volcanic eruptions, hurtranes, even the most deadly of man-made explosions such as the Halifax disaster of 1916. It may move thousands of cubic mites of solid rock, change hundreds of miles of geography, shift mountains, rearrange ruvers and harbors, create lakes or destroy them, open miles-deep cracks in the ground and grind millions of tons of rock to powder—all in the winking of an eye.

Before men can even tell which way to run it is all over-buildings are down, hundreds or thousands dead, cities in flames. The tremor in Southern California in 1933 lasted only seven seconds but killed 120 people. In San Francisco 40 seconds sufficed to start the ruin of a metropolis. In Chile a little while ago the shake went on for two minutes; 50,000 died and as many more were injured. Through the pages of history runs a red trail of blood and fire to mark where man, the luckless interloper, has gone down before the onslaught of the laboring earth, Lisbon, Messina, Port Royal, Charleston, Tokyo, Helena, Chillan-the record is jammed with tragedies. One moment a teeming city, the next a shambles, like a Sodom and Gomorrah struck down by divine wrath.

Yet earthquakes are not "acts of God"

A Small Percentage Added to Building Costs for Adequate Bracing is Changing Earthquakes from a Dreaded Horror to an Interesting Phenomenon

By DAVID O. WOODBURY

at all. They are as normal as rain and armor frequent. Mothe Earth twitches constantly like a sleeping dog and cares on more for the effect than he. Sriamingraphs distributed throughout the world record an almost steady shiver of the ground—too minute to be felt, mostly, but proof of incessant activity below. In an average year Japan is visited by some 12,000 tremors, with other countries around the Pacific basin playing close seconds.

NOR are major quakes uncommon either. There are on the average 50 of them every year throughout the world. In Chile severe shakes occur every month or so, often accompanied by destructive seismic sea waves. Even in solid old New England there have been 350 earthquakes of major intensity since Colonial times. Earth tremors are as obedient to the law of averages as the cycles of the weather. In dangerous areas, such as Japan, Southern California, and South America, seismologists keep a continuous record of the uneasy earth and can foretell the probability of future quakes as accurately as an insurance company can predict the life expectancy of a

Earthquake disasters usually overtake

the public without warrang, but scientus; are rarely surprised. Seismologists in Southern California, for example, are momentarily expecting another major shake, with an intensity say great, possibly, as the one which wrecked San Francisco in 1906. It may come tomorrow, it may not come for years. But they know that it will come sooner or later. Whether a great disaster will follow, as in Chile, depends upon where it strikes and how much protective work has been done in the meantime.

For people do not need to die when the earth shudders, nor do cities need to be trained. The earthquake, says the scientist, is rarely destructive in itself. It is man's perastence in building inadequately—bis refusal to eliminate the death-traps that he has deliberately exceed for humself. Science is slowly instructing a public loath to face the simple engineering facts. Little by little it is convincing the people that if they must live where continents are still in the making they must realize their danger and prepare.

A long and difficult problem of education this is, and one that must be founded on an exact knowledge of earthquakes and of how and where they strike. Admittedly, protective seismology has only just begun. Fifty years of research has meant no more than a start.

Though the effects of the shuddering earth are gigante, the causes are most difficult to find. This is because they he so far down in the bowels of the earth that they can never be studied at first hand. Only the comparatively minute vibrations which reach the surface can be used to interpret what goes on underneath. Ironically, man's entire knowledge of the deep interior comes from a study of the tremors which destroy. Without them he would know luttle of the depths below a few thousand feet.

Farth has a solid crust 20 to 40 miles thick. Unlike the crust of ice on a pond it does not float on liquid material below it. If it did, earthquake vibrations would not be transmitted as they are through the center of the globe A few miles down science pictures the pressure and temperature of the overlying rock to be so tremendous that the material is actually made plastic, like tar in a bairel. On this, geologists think, the hard outer shell slips and slides like scum in obedience to forces unknown Erosion, the gradual shrinking as the interior cools, the release of radio-active energy, the tidal pull of the Moon-any or all may be the fundamental causes, no one vet knows But the effect on top is certain. The thin hard crust on which we live is subjected to continual twisting and bending, stretching and compres sion, and is tortured into ridges and hollows as it tries to accommodate itself and fulls. The result as seen by the inhabitants outside, is the mighty process of mountain building.

IT takes many millions of years to create mountains from a plan Surface movements may be imperceptible within the lifetime of one man, yet in accumal laded centures they are hige. The Himalayas themse lives were presumably made that way. The important fact is that the earth's crust is never allowed to rest. Over and over again great pressures are built up, over and over they reach an intensity no rock can stand Then all at once something lets go, and the fringes of whole continents may move.

Eons of this abuse have ruddled the earth's crust with fissues which run down 20, 30, even 40 miles. These are known as "faults"; they do not show on the surface like kinfe-cuts in home-made candy, but are filled in with pulverraed rock and debris and often only geologists can recognize them. The great San Andreas Fault in California is largely hidden, and is principally identified by mountain structures which have been rent asunder and moved past one another as much as 20 miles.

Mountain building is mainly vertical but the strips of land between faults are moving horizontally also, and at considerable "speed." The friction of two neighboring blocks of crust is very large and as they try to slide past each other they stick fast and cannot move. Gigantic stresses are built up and the loose top layers of sand and boulders along the fault are actually compressed and sprung out of shape as if they were made of rubber. A fence or road across a fault often shows this condition by being bent into the form of an "S" When friction can hold the pressures in check no longer there is a roar and a shudder and whole cubic miles of rock spring into life and serk past each other. The forces are so huge that these "clastic rebounds" invariably overshoot the mark. The earth then jerks and jerks again till the strains are for the moment eased. This is an earthquake: no wonder, then, that luckless human witnesses and their puny buildings are often destroyed!

BUT the actual slip along a fault is not in itself the destructive element. It is the aftermath of vibration which does the harm. If all the cities in earthquake zones could be built on solid rock there would be no disasters, for the rock itself shakes only a fraction of an inch The danger has in the deep deposits of alluvial soil which skirt the mountain walls. The loose rocks and sand are saturated with ground water and the conglomerate acts like a telly, intensifying every earthquake vibration to hun dreds of times its original amplitude Thus the principle of resonance, which is so useful in a radio set, in earthquake country becomes the sinister devil which destroys everything in its path.

There is always a center of disturbance on a fault where the actual slip begins. It is usually miles below ground and the movement may not reach the surface at all. But the vibrations do, and they spread out in every direction, often traveling clear through the earth and out on the other side. The whrations come three disturbance to the feel, but which shakes the air so rapidly that which shakes the air so rapidly that

it creates the horrible roar often heard just before a quake. Next, a vibration of nuch lower frequency which rattles dishes and chandeliers but does little harm. And finally, the slow and deadly set of waves, traveling like rollers in the occan along the surface of the ground.

These are the ones that fling the trees about as if in a great wind, open and close huge cracks in the earth and send people staggering and often deathly seasek as they go. These are the ones that set the buildings rocking and topple them down on whomever is in their path.

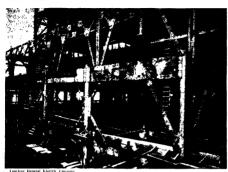

Science bases its entire knowledge of carthoughes on studies of these vibrations, transmitted through the earth and picked up by delicate seismographs hundreds or thousands of miles from the center of the disturbance. In principle the seismograph is simply a heavy weight suspended like a pendulum, holding a stylus against a piece of smoked paper. When the earth piggles the paper piggles with it while the weight stands still and thus a record of the vibrations is scratched on the sooty paper. In highly refined modern instruments the recording is done electrically through vacuum-tube amplifiers and a beam of light on photographic

The successful analysis of an earthquake depends upon how accurately the center of disturbance can be located in the earth. This is a problem of triangulation in three dimensions and requires a detailed interpretation of vibration records taken simultaneously at widely separated points. A network of seismo-

graphic stations is gradually being built up all over the world and a central computing headquarters has been established in Oxford, England. Records are constantly flowing to this station from everywhere and the data are correlated so as to give the position of each important earthquake as it occurs. But it is a long and

Showing what is meant by adequate diagonal bracing against earthquakes. The Edison Building in Los Angeles with steel frame and are-welded seismic bracing

complicated mathematical job and sometimes years clapse before exact results on any one tremor can be published. In the United States similar work is done in Washington and St. Louis.

In foculities of high earthquaked danger, such as Japan and California, much more advanced measures have been taken, and well-staffed central laboratores are maintained, surrounded by a network of recording slations located with special reference to the existing faults. The work of these organizations is gradually making at possible to predict where earthquakes will occur and to show how protection can be achieved

SEISMOLAGISTS drude the world into two narrow earthquake belts, one circling the Pactic Ocean, the other Spain to the Orient. Minor belts are found along the castern seaboard of the United States and in the Miss-stippi basin. At any point within these belts destructive quakes may occur at any time, and there is no positive assurance that they won't occur outside them also.

Disastrous tremors are uncommon in America except in the far west, although plenty of strong shakes have been recorded. The geological formation in the east is the most ancient in the world and its worst shaking was over before man arrived. The middle west is almost as stable Nevertheless, the greatest quake in American history took place in New Madrid, Missouri, in 1811, and only missed killing thousands because it happened in the wilderness. North Dakota is the one state where a destructive quake has never been recorded. There is no guarantee that even that will escape forever.

New York City is virtually immune,

for it is built on two deep and aged rock strata untroubled by faults Boston, on the other hand, is not far from the great Fundy Fault in the Gulf of Maine, and major shakes have occurred there. The hazard is considerable, because the whole Back Bay section of the city is built on muck numbed from the Charles River. A quake as severe as the one that struck in 1755 would probably cause severe damage and heavy loss of life. Philadelphia, Chicago, and many other large centers are similarly built on made land. which is ideal shake material, and might suffer severely even in a minor earthquake Charleston, South Carolina, was badly damaged in 1886 by a small disturbance because it was built on poor foundations Nevertheless, the risk is considered so slight in the eastern half of the United States that almost no one carues earthquake insurance. In the whole city of New York, for instance, only a scant handful of buildings are so covered.

By long odds the greatest danger point in America is in Southern California and it is here that a typical earthquake program is being built up. The work centers around the Carnegie Institution's seismographic laboratory at Annandale, with assistance from the Coast and Geodetic Survey and the laboratories of various universities. Intensive study was begun after the San Francisco disaster but it got little support from the public till their bad fright at Long Beach in 1933. Since then the Earthquake Commission has become an accepted institution and has made use of every opportunity to urge utmost preparedness against the serious earthquake which is surely com-

Numerous seismographic stations are scattered about the state and their records of vibrations are ingeniously synchronized by photographing radio signals alongside the tracks drawn by the tremors themselves From these timed records it is comparatively easy to compute the direction from which the vibrations come and their speeds, and hence to keep informed of the slips occurring on the seven faults that cross the state. The government, also, has creeded a large number of monuments or bench marks on high ground and these are surveyed annually to indicate the general movements of the earth

W/HENEVER a major earthquake occurs, most of the delicate instruments nearby are put out of commission and information has to be gathered from such random sources as the direction of fall of gravestones, the pattern of cracks in the soil and the movements of buildings and their contents, Though eyewitness accounts are highly unrehable, a postcard poll is usually taken with the hope of obtaining enough data to form reliable engineering opinions. After a serious quake one man sent in a sketch of the wandering course of the gas stove around his kitchen floor. It gave the scientists an excellent picture of the earth movements at that spot in the devastation area. Recently, "strong motion" instruments have been installed around Los Angeles and hit or-miss observations are no longer so necessary

But these scientific studies, valuable as they are for the future, do not interest the citizens as much as the campaign for protection which the Earthquake Commission is also fostering. The last serious quake, at Long Beach, occurred just before six in the evening. If it had happened carlier thousands of school children would have been killed, for not a school for miles around was left undamaged and many were destroyed The public instantly clamored for advice on how to rebuild their schools so that they would not fall again, and with the help of the chambers of commerce and insurance companies, a rigid building code was worked out and passed by the Legislature. Every school in California has been rebuilt or strengthened since; in Los Angeles alone it is estimated that \$150,-000,000 has been spent.

The rule for building protection is simple but often expensive, make them heavy and rigid and tie them to firm foundations. A shake is destructive because its third type of vibration closely coincides with the natural period of sway of the average building. Heavy, willowy buildings especially are prone to fall in step, and their own elasticity amplifies the motion until they collapse. Large reinforced structures usually do not topple themselves but send tons of ornamentation in a deadly shower to the street. Property owners are warned not to decorate their buildings with anything that can be shaken loose Civil engineers are

EARTHQUINE RISK IN CALIFORNIA

that question with any definiteness. A great shock may come soon, or within a decade, or not till after more than a decade But it will come

I have been asked what I would do in the circumstances and I have answered that I would try to do the sensible thing I would see to it that my house was reasonably well tied together so that my family might sleep and live in security, and I would endeavor to arouse public interest in demanding that school buildings, stores and other structures were made safe also against wreck and fire hazard. And I would take out earthquake insurance

San Diego District San Diego and Los Angeles have so much in common in their earthquake history, it might at first sight seem appropriate to describe as one province the whole coastal plain, together mountain ranges that rise from

A prophecy which caused a rumpus, and its happy aftermath. When, in December, 1923, the noted seismologist Prof. Bailey Willis, of Stanford University, published in the Bulletin of the Seismological Society of America the warning in the top two lines of the reproduction above, and the advice in the succeeding seven lines, incensed real estate men rushed to the head of Stanford University and (unsuccessfully) demanded recantation or discharge. Ten years later came the first major quake, Long Beach (Prof. Willis predicts another), and this made it possible for science to gain a long-denied hearing. A joint report of science and business (see below) was issued and safe buildings were begun. Before buildings can be altered, human traits must be altered-the bigger task

the Public:

In response to official requests from many representative technical and civic organizations, the Joint Technical Committee on Earthquake Protection tion was organized after the earthquake of March 10, 1933, to consider ways and means of minimizing loss of life and property damage in the event of another earthquake of equal or greater intensity

We now present to you, in the form of this summarized report, our belief as to the seismic hazard in this region and our opinion as to the proper balance between the degree of protection to be afforded life and property and the cost of providing such protection

We sincerely hope that the lessons of the Long Beach earthquake will not be forgotten as were the lessons which should have been fixed indelibly in the minds of all by the earthquakes of the past

> JOINT TECHNICAL COMMITTEE ON EARTHQUAKE PROTECTION

asked to design the columns and founda-

tions of new structures so rigidly that their natural period of vibration will be much faster than the earthquake's tremor. Buildings of this kind in Tokyo came through the holocaust almost untouched, but in Chile whole cities built

of spineless adobe and brick were ground to powder, the inhabitants beneath Small homes of wood are unusually sturdy for their weight and rarely become death traps. They may be thrown askew on their foundations but are likely to remain in one piece.

As for personal conduct during an earthquake, say the scientists, the first requisite is to avoid panic. The victims are likely to be the people who rush screaming to the street only to be crushed by falling debris. The safest place when the shake begins is a solid arched doorway or an inside corner of a room that is well braced. Most natives of California and other danger spots know this, but by no means all of them practice what they know when the horror begins.

An important point to remember is that a severe earthquake is sure to be followed by after-shocks, some of them nearly as severe as the original. People who have deshed into the ruins to save victims are often caught by the toppling of buildings weakened but still standing. Thousands in Chillan met their death in this way.

OPEN flat spaces are usually the safest, for rarely does the ground "open and swallow men up," as it was reported to have done in San Francisco. But open spaces in the hearts of cities are to be mistrusted. In the Tokyo quake 40,000 homeless people were herded by the Chief of Police into a broad park especially maintained for this emergency. bringing with them what few belongings they could snatch from the ruins, Within a few hours they were surrounded by flames, their tinder-dry baskets of clothing caught fire and they were incinerated to a man. The Chief of Police committed hara-kiri that same night, from remorse.

In many earthquake countries people firmly believe that shakes do not come without warning. There is still a dogged faith in signs such as "earthquake weather." Seismologists find some justification for this but warn that actual predictions of time and place are surely the work of charlatans. In Japan, sometimes, low barometric pressure and high winds precede a quake. If there is any connection it is because the earth is in so critical a state that wind pressure against the mountain walls is enough of a "trigger force" to set the quake in motion. Occasionally, a few minutes or hours before a tremor, the land will begin to tilt slowly, but quite as often the land does not tilt, nor does the weather give any sign.

Far better than believing in signs is to work for preparedness. The responsibility for this lies mainly with the city governments, which must learn to face the menace of earthquakes regardless of civic pride. To let quake protection lag is misplaced economy; worse, it is an open invitation to disaster. Nor is a thoroughgoing program of protection prohibitive. As the noted engineer, R. R. Martel, said in addressing a Los Angeles meeting recently: "If you will put only 10 percent more into the cost of your buildings, the chamber of commerce can adopt the slogan; 'Come to California to enjoy the next earthquake."

TINTED LENSES

Sun Glasses Should Give Adequate Protection Yet
Maximum Visibility . . . Objective is to Eliminate
Rays Which Do Not Contribute to Sceing

Entron's Notis: Increasingly under use of sam glasses to eliminate glare, especially for sports and automobile diring, makes necessary a uniting that only certain types and colors will gue the protection that is sought, in the following article are summarized the reasons for wearing such glasses, what they must do to be effective, and the types that will be most effective for use nith normal eyes.

TIKE other organs of the body, the geyes have had a difficult time keeping pace with the rapid strides of civilization. We have turned night into day, giving the eyes little rest from the continuous bombardment of light, Although the eyes are about as adaptable as any other organ, they have a great variation in sensitivity. The deposit of pigment in the choroid, retina, and it is is as variable as are the human races, yet has a definite relationship to a person's tolerance of light By adding pigment to the eve in the form of a tinted lens, the enhanced sensitivity of the nervous conducting mechanism of the eye is allayed There are many pathologic and psychogenic states which respond to an absorption lens of the proper pre-cription There are numbers of tinted lenses on the market, many of which are offered without any pretense of scientific co ordination with the eye.

The normal eye soes primarily with

the yellow and yellow-green components of the spectral light—the most humano-part of the spectrum and the one in sharpest focus for the yellow, the eye is slightly out of focus for the extremes of the yellow, the eye is slightly out of focus for the extremes of the yellow free the present of the yellow focus for the extreme and to the besonfierd may result from sharp focusing of either of these extreme rays on the sensitive layer of the retina and a tinted lens of the neutral type any remove these rays entirely of diffuse them. A neutral type is one which absorbs equal proportions of all colors of light, as opposed to selective absorption of certain radiations.

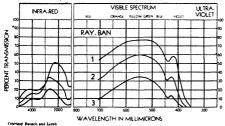

Parksons with normal eyes who wear are usually more confortable with one of the greensh types of optically ground and polshed leness whose properties are definitely established and the three measurements of which are held within close limits. Since the maximum of the visual response is in the yellow and yellow, and the work of the work of the wide spectrum, a lens which transmist these radiations will give the utmost that may be expected in visibility with as little light loss as is possible with adequate protection.

A few types of these glasses are not able for their elimination of both the ultra-woolet and infra-red radiations, neither of which contributes to seeing. The dangers of these two radiations are well known in industry and they are

suspected of contributing to several occular diseases but their exact effect in sunlight is still a subject of study. Infraer aduation produces heat and one is warned by the burning sensation felt in the eyes. Most of the ultraviolet radiations are believed to be stopped in the cornea and crystalline lens, but any effect of them is the more mosdows because the reaction is not felt for hours.

Yellowgreen and bluegreen glasses appear to merese visability by brightness-contast, due to the climination of a scattered high of short wavelengths, just as a photographer obtains fine pretures of clouds and distant scenes by lusing a yellow green filter. The aerial photographer gets sharp photographs of enormous stretches of country by using a filter which excludes all but the infrared rays. All those devices function largeby by removing the veiling effect of shortwave light scattered by the intervening atmosphere.

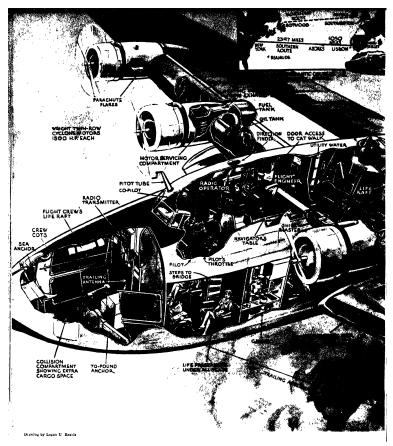

The various tints of glasses on the market result from the kind of oxides added to the glass-forming constituent, usually a soda-lime batch, Cobalt oxide produces a blue glass, chrome and uranium oxides, green glass, gold oxide, tuby, silver oxide, yellow, manganese oxide, pink or violet, and cerium oxide, brown All of them absorb different portions of the spectrum. Amethyst glasses have a strong absorption in the blue region and modify colors to a great extent Amber and brown glasses absorb the blue and violet, flatten the vellows and intensify the reds, but their transmission of infra-red is high. Blue glasses of the cobalt types absorb selectively in the green, yellow, and orange-red. They also have high transmission of the infrared. Crookes glasses, brought out in 1913 by Sir William Crookes, were a great advance over previous absorption lenses, definitely absorbing both the ultra-violet and infra-red rays. Although widely prescribed today they are not so popular as formerly, due to a marked selective absorption in a narrow band of the visible spectrum, caused by the use of the rare carth, didymium. In the darker shades they absorb heavily in the region of maximum visibility

Courtag Bassets and Lords

Light transmission of one type of sun-glass lens, in three different shades.

Note high percentage in visible, low in infra-red, and opacity to ultra-violet

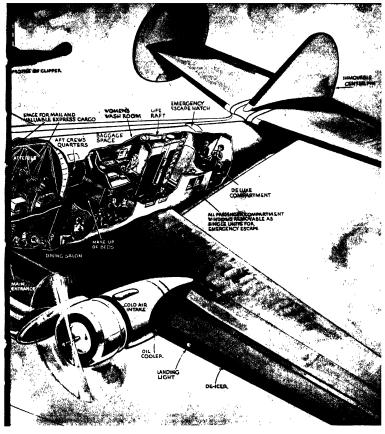

In the Transatlantic Service

WITH wings spreading 132 feet and hulls 106 feet long. Beeing Clipper ships have inaugurated transatlantic airmud service, at its expected that, by the time this issue reaches the reader, transatlantic passenger service will have been established on regular schedule. Already six of these huge ships have been built. Two of them are in use over the Pacific, while the other four are to be used in the Atlantic flights Our drawing shows the details of these ships, which have been designed to offer the utmost un confort and safety.

to the passenger. When used for daytime flights, 74 passengers can be carried; berths made up from triple-seat davenports will accommodate 40 passengers for night flying. Sound-proofing is extensively used throughout the Clippers,

Sound-prooning is extensively used inrougnout the clippers, or crew quarters as well as in passenger compartments. Air conditioning assures comfortable temperatures at all times. A completely equipped galley serves hot meals while aloft. Designers of the Clippers have foreseen every possible emergency and have made privisions for insuring the safety

of passengers and crew at all times, Individual life preservers are placed under all seats; life rafts, each capable of supporting I/O persons, are radily available when needed. A kite, stored above the after crew's quarters, can be used as a signaling medium in case of a forced landing. Complete fire-fighting equipment is provided.

The inset map at the top of the drawing shows the two routes that have been surveyed from the United States to Europe. It is possible, however, that, due to weather conditions and the desirability of taking advantage of favoring winds, deviations from direct ourses will be a matter of routine when transatlantic flights are on regular schedule. In fact, on one of the first mall flights, the Yankee Clipper, first of the ships to fly the Atlantic, made a 300-mile detour to the south of her normal course when adverse winds were encountered. This detour made possible a stop at Bermuda.

More technical details of the Boring-314, as ships of this type are known before they are christened, will be found in issues of Scientific American for July 1938 and May 1939. As is usual in the design and construction of new plane types, changes have been introduced as work progressed and it was found that such changes would be advantageous for one reason or another. For example, early plans for the Clippers did not call for the immovable center fin of the tail assembly. In fact, test flights were made without it and it was not m-stalled until experience indicated that it would be desirable.

McDonald Observatory

THERE is no more successful example of human co-peration than is so and the stronger of the succession of the succession of the trule of reson prevails. Our political, national, and racial differences, however important, have really very little significance beyond the limits of the Earth's cance beyond the limits of the Earth's tamosphere. Here we cannot act or experiment, but must be observers only but we may still be active observers, seeking eagerly for the best opportunities and the most powerful means of investigation

Many kinds of co-operation among astronomers are an old story, such as the division of a great field of observation, such as cataloguing the stars, into parts undertaken by different observatories; and the continual exchange of information, published and often unpublished, is the very life-blood of our growing knowledge. The smaller institutions, in particular-as the writer of these lines has abundant reason to acknowledge with gratitude-are continually indebted to the great observatories, which, gathering information far faster than the photographs can be worked up, are most generous in supplying material for theoretical workers elsewhere.

A new and very effective type of cooperation has just been formally inaugurated in the principal astronomical event of the past month—the dedication of the McDonald Observatory.

Forty years ago, Mr. William J. Mc. Donald, a hanker of Paris, Texas, became deeply interested in astronomy, as an amateur student. Upon his death 1926—leavage no near relatives—he left the bulk of a considerable fortune to the regents of the University of Texas "for the purpose of aiding in erecting and equipping an astronomical observatory, to be kept and used m connection with and as a part of the University, for the study and promotion of the study of astronomical science."

When certain legal problems were settled, the University found itself in possersion of about \$800,000, and a major problem arose. This sum was major problem arose. This sum was enough to provide for the construction of a really great relescope, and equip it with the accessories required for modern research: but if this was done, there would be very little left to provide salaries for astronomers to observe with it. If enough endowment were set aside to provide for an adequate staff, only a telescope of moderate capacity could be built with the remainder.

Rather than suffer this limitation, it was at first planned to let the fund ac-

The Large New Observatory in Western Texas Was Made Possible by an Amateur... An Admirable Site, An Efficient Housing and a High-grade Telescope

By HENRY NORRIS RUSSELL, Ph.D. Chairman of the Department of Astronomy and Director of the Observatory at Princeton University Research Associate of the Mount Wilson Observatory of the Carnegie Institution of Washington

cumulate until it became adequate. But, at the same time, the University of Chi cago found itself facing a similar, yet curiously different problem The Yerkes Observatory was rich in staff, and less so in equipment. Under the new director, Dr. Struve, a very able and enthusiastic group of young astronomers was being assembled. The great refractor of the Observatory-the largest in existencehad been built when the possibilities of great reflectors were not yet appreciated. Indeed, it was the construction, shortly afterward, of the 24-inch Yerkes reflector (the first to be equipped with a mounting conforming to modern standards of accuracy and convenience) which brought the reflecting telescope back into its own. A great reflector was badly needed to extend the equipment of the Observatory; but there was no money for it.

Some genius realized the complementary character of these two problems -each was the solution of the other. With the enthusiastic approval of President Hutchins of Chicago, and the late President Benedict of Texas (himself an astronomer) plans were developed for a close co-operation between the two universities-culminating in a formal agreement covering a period of 30 years According to this, the University of Texas was to build the observatory and the University of Chicago to staff and operate it-equitable arrangements being made regarding running expenses, and publication of the results. This close partnership between two independent institutions-one a state university, the other privately endowed-is a novelty, and promises great things.

The next problem was to find a site for the new observatory. Fortunately, Texas is a large state, and its western portion extends into the semi-arid region where high altitudes and clear skies may be found. After the usual extensive reconnaisance, a site was chosen on Mount Locke, in the Jeff Davis Mountains, in the county of the same name, The peak 14 6800 feet above the sea, with slopes not too steep to allow a well graded road to be built to the very summit, and covered closely enough with trees to protect the ground from overheating by the Sun. There are some higher peaks in the region, but these are either too remote or difficult of access, and the Observatory commands a clear horizon in every direction. A well drilled on the slope, 600 feet below the summit, provides an adequate supply of good water. About 20 miles of good—though not paved—road lead to the town of Fort Davis where adequate supplies can be obtained. The nearest railroad is 20 miles farther.

The necessary conditions of habitability are therefore met—and well met. It is a cattle country, of good-sized ranches. (This phrase has a special meaning there—one may hear a cattleman say: "Oh, he hasn't a big ranch—only 80 sections.")

The observing conditions are also excellent. The seeing is good, the air clear, and the site is as remote from city lights and man-made glare as could easily be found. From the summit the view ranges in all directions over wooded mountains separated by tawny grass-lands, with hardly half-a-dozen human habitations in sight. Long before the great telescope was erected, Struve and Elvey had proved the advantages of its location by observations of the spectra of faint diffuse nebulae, and of the brightness of the zòdiacal light, and the faint diffuse illumination of the night sky-which could only be successfully accomplished in the clearest and purest of skies.

The Observatory itself crowns the very summit. A glance at it—or at a picture—shows one difference from most others. The walls of the cylindrical sub-structure below the dome are pierced with many windows. This reveals a very nice piece of architectural efficiency. To get the line of vision clear of the disturbed air near the ground, the great telescope is usually mounted at a respectable height, so that the floor of the dome is as far up as the third story of an ordinary house, in all their large observatories, the space under

this floor is simply vacant. Part of it may be used for constant-temperature rooms, and other scientific purposes; but most of it resembles the huge space below the dome of the 100-inch telescope at Mt. Wilson, which was once described as "providing ample parking space for the automobiles of the mechanics and the walking-sticks of the astronomers." On Mount Locke things are different The large available space is divided by floors. and provides for a library with stacks and a main room big enough to hold 80 to 100 people-it was crowded at the conferences!—also offices for the principal members of the staff, and several small bedrooms for astronomers who come down from Yerkes for special work The permanent members of the staff have houses on spurs of the mountain a little below the summit - and the writer cannot refrain from expressing his admiration of the good judgment which has made these houses really attractive

MOUNT LOCKE is remote enough to make it necessary for the permanent observers to live on the mountain. There is no near by town, as at Pasadena or Victoria. Living in a small isolated mountain community has some inevitable disadvantages. They are far less serious than they once were-no one who has heard it will forget the story of the young son of one of the astronomers at the Lick Observatory, who lay unconscious, after a bad fall, for three hours, while the doc tor summoned by telephone toiled up the steep winding road as fast as a team of good horses could take him. Even today there are some inconveniences-but they count for less when the things which can be provided to make life pleasant are available

But all else on the mountain centers, of course, upon the great telescope-the second in the world. The 82-inch mirror is of Pyrex glass- -of very low coefficient of expansion-and has been figured with almost ideal precision. Thorough tests by the veteran observer, J. S. Plaskett, show that the deviation of its surface from the true form averages only seven ten-millionths of an inch-one thirtieth of a wavelength of visual light. The "diffusion disk" resulting from the failure of all parts of the mirror to bring the light to precisely the same focus is considerably smaller than the diffraction disk arising from the properties of the light-waves themselves-so that a still more perfect adjustment of the figure would gain nothing practically.

The mechanical mounting of so large as instrument is a difficult enguneering problem—the moving parts weigh 45 tons. The "cross-axis" design has been adopted—in which the principal polar axis extends between two separate piers and the telescope tube is at one side of this, counterbalanced by suitable weights on the other.

The 38-3teh mirror, 12 Inches thick, after aluminizing. From left to right: H. L. Cook, director of the Wainer and Swasey Company's natrument department; C. A. Robert Landin, director of the optical department, who figured the mirror; Dr. John S. Plackett, director emeritus of the Dominion Astrophysical Observatory, who tested it, George A. Detker, works engineer. The food ratio is f

This type of mounting has the great advantage that all parts of the sky may be observed-including the pole and the southern horizon Great reflectors, with mountings of this sort, existed already at Victoria, B. C., Delaware, Ohio; and Toronto, but the new instrument has one great advantage that these lack-a coudé device for spectroscopic work. When this is in place, a plane mirror, inclined at 45 degrees, reflects the light from the telescope tube at right angles, through the hollow declination axis, to a second mirror, which sends it down the interior of the hollow polar axis. It comes out at the lower end of this at the same place, no matter to what point in the sky the telescope is directed. The rays are received in a room maintained at constant temperature, in which very powerful spectroscopes, and so on, may be installed.

The 100-inch mounting at Mt. Wilson was designed with an arrangement of this sort, which has proved increasingly valuable and useful; but the engineering problem of adapting this to the cross-axis type of mounting had not previously been solved. It was necessary to alter the construction of the main bearings, about which the telescope is turned to reach northern or southern stars, so that, whatever its position, the light might have an unobstructed passage The unusual position of the great counter-weight at the upper end of the polar axis rather than opposite the tele-scope-bearing was part of the same scheme.

The instrument has also the usual Cassegrain arrangement in which the light is reflected back by a convex mirror through a hole at the center of the great mirror, to form a large-scale image, and an ingenious device for taking photographs at the primary focus

in the middle of the top of this main tube—thus avoiding the loss of light by reflection at a diagonal mirror. The moving platform by which the observer may reach the upper end of the instrument in any position is also very efficiently designed.

The latest incthods have again bein used in the "drive," which turns the great mechanism about the polat axis to follow the stars. This is entirely electric, and regulated in rate by the precise and effective vacuum-tube control devised by Dr. McMath. It can be adjusted so as to allow for the changing effects of reaction as the stars change their altitude, and the test of actual operation described in "drives and the stars change where all the stars change with the stars change with the stars of the stars change with the stars of th

shows that it is "practically perfect."
It would be of little value to have
even so powerful an instrument if there
were not a good prugram of work to be
done with it. Here Dr. Struwe—now
director of the McDonald as well as the
Yerkes Observatory—has outlined planwhich should meet the hearty approval
of all astronomers. Problems which demand the utmost light-gathering power
such as to extend the boundaries of
our knowledge of the "universe of

our knowledge of the "universe of galaxies"—are wisely left to the 100-inch telescope, and the 200-inch when it is finished.

But there is an immense field of work

But there is an immense field of work in the study of individual stars, and especially of those unusual and interesting objects which are found here and there among the faint stars. With an excellent outflit of accessories—spectrographs and the like—the McDonald telescope has already, before its formal dedication, revealed new and important things. Its admirable site, its excellence of mechanical and optical quality, and, above all, the skill and enthusiasm of the staff, make a long career of usefulness certain.—Princeton, June 1, 1939.

Under The Nieuwe Maas

AT an outlay of approximately \$8,225,Modo, Rotterdam is building a subaqueous tunnel that differs radically
from other structures now in use as
underwater traffic routes. This single
structure, which passes beneath the
Nieuwe Mass River, is designed with
four passageways—one for pedestrans.

one for cyclists, and two for motor vehicles. As an engineering undertaking, the tunnel is unique in a number of particulars. Work on it is now in full swing, and some of its main sections are in advanced stages.

To appreciate why Rotterdam is this equipping her self, one should have some understanding of the extent of this center of Holland's maritime commerce. The port is situated less than 20 miles

inland from the North Sea at a point where tributary river routes and various canals have made the harbor accessible to vast interior regions of Holland, Ger many, and Begjuin. Rotterdam's secial, industrial, and commercial expansion during recent decades has protoundly altered her intra-urban traffic problems.

At this time, 30 percent of Rotterdam's people, many of her foremost industries, and the greater part of her shipping interests are located on the south side of the stream which bisects the post from east to west. The old Willems-Bridge, built in 1878, still remains the Unique Tunnel at Rotterdam . . . For Vehicles, Pedestrians, Cyclists . . . Rectangular . . . Sections Built on Land, Then Floated Out and Sunk in Place

By R. G. SKERRETT

Cross-section of under-river part of tunnel in which all three classes of traffic will be accommodated Pussages for motor vehicles at (a, a); cyclists (b), and pedestrians (c)

single crossing available to pedestraine vehicles, and street railways. That structure is now not centrally located in relation to the most active sections on the two sides of the river, and it is overtaxed at peak periods of traffic. To some extent relief has been afforded by crossriver ferius. But these have operating diawbucks. The city authorities have for vears recognized that one or more additional permanent crossings should be constructed; but the question was what kind would best meet the requirements. Bridges, of course, have been considered as well as tunnels by the engineers

of the river is low, but a low bridge, with a draw, would not answer because its frequent opening would halt and congest the flow of motor vehicles. A high bridge, with ample under clearance for the masts of any ships using the port, would require very long approaches in order to assure acceptable gradients for vehicles. Such a bridge would have to have a length of 25 miles, and its approaches would be too far inshore to be readily accessible to motor trucks, for example, plying between the docks on one side of the stream and distributing points on the other side The engineering experts, accordingly, decided in favor of a subaqueous tunnel capable of providing annually for the transit of 8,000,000 vehicles, and daily

In and out of Rotterdam

nually nearly 34,000,000 short

tons of freight in overseas

commerce, and the Nieuwe

Maas, now familiarly known

as the New Waterway, is

threaded continually by ocean-

going craft There are, be

sides, well-nigh ceaseless

movements of vessels of other

sorts. The land on both sides

THE route chosen for the tunnel crossing is some distance downstream from the Willems-Bridge, and is intended to link what is known as the Park section of the older part of the city with the Charlos area on the south side of the river, where it will have its portal close to the very busy docks. The tunnel will also serve as a link for much used motor highways leading to and from other important cities of Holland The low land on each flank of the waterway permitted the designers to keep the total length of the undertaking within approximately 4800 feet; yet the nature of the ground both on shore and in the bed of the river has presented major difficulties

use by thousands of pedestrians and

cyclists.

The project may be subdivided into two open-cut ramp approaches; two land tunnel sections; two ventilation build-

Unstable soil in the deep trenches of the approach ramps made necessary use of large numbers of piles. Deep-well pumps are operated continuously to keep the trenches drained. Each finished ramp will be a great reinforced concrete trough

ings, one at the water's edge on each flank of the river; and a central subaqueous tunnel section, which under-runs the stream and which connects with the underwater foundation structure of each of the ventilation buildings. The river tunnel has a length of slightly more than 1917 feet, and the adquiring two sections of land tunnel are, respectively, 902 feet and 902 feet, in length From end to end of the tunneling, including the substructures of the ventilation buildings, the undertaking will measure

The land tunnel sections are being built in deep open cuts, the foundations for the two ventilation buildings have been carried down to their prescribed depths at the shore fronts by means of pneumatic cassons, and the under-river tunnel will be assembled by what is described as the "sinking method" That is to say, each of the nine separate sections of the subaqueous tunnel is built up to a degree on shore, then floated out into the river for completion in a buoyant state and, when ready for final placing in the river, it will be towed to a point directly over its given site and sunk into a trench excavated in the river hed. The substitution of this procedure for the familiar shield-and-pneumatic method of tunnel driving is because the soil of the tiver bottom is too loose and sandy to permit the use of compressed air unless the tunnel were carried much deeper to reach firmer subsoil Other subaqueous tunnels have been constructed in a measure along kindred lines, but even so, the Rotterdam tunnel represents some novel and very interesting departures in practice

THE two sections of land tunnel air designed only for the passage of motor velucles, while the river section will provide for the passage of pedestruccyclests, and motor vehicles. The pedetrians and cyclists will enter and leave the river tunnel through connections leading to and from surface buildings aljoining the ventilation buildings al-

Each of the nine units forming the under-river tunnel is a great reinforcedconcrete block that is perforated from end to end by four traffic passages and numerous lesser longitudinal chambers for the transmission of fresh air and the withdrawal of vitiated air. Each of these box-shaped elements has a length of slightly more than 200 feet, a width of about 81.25 feet, and an exterior height of 27.53 feet. The roadway in each of the two vehicular passages has a width between curbs of 19.7 feet-affording room for two traffic lanes; and the ceiling is 13.77 feet above the roadway. The passageway for cyclists has a width of nearly 16 25 feet, while the passageway for pedestrians has a width of about 14.34 feet.

To protect each of these reinforced-

A partly finished tunnel section being towed from the drydock, where it was built to the finishing slip where it will receive the remainder of its concrete body. This view serves to give a good comparison of the section's size

concrete blocks from water penetration. it is to have a coating of welded steel 0.236 of an inch in thickness covering both sides and the top and bottom sur faces. As an extra protection against corrosion, that steel is to be covered with a thin layer of concrete. The working schedule has called for the simultaneous construction of three such tunnel sections in the Municipal Building Yard at Heysche-haven. When a certain stage of partial completion has been reached, the divdock is flooded, the sections are floated out into the river and towed to Waalhaven, where the rest of the work is done preparatory to sinking.

To make it possible to float the sections from the divdock and to shift them to the finishing slip, each section, after the concrete is poured to half height in the drydock, is sealed at each end with a temporary reinforced-concrete bulkhead, and closed along each side with a temporary timbered bulkhead—all the bulkheads extending high above the surface of the water and giving the section the appearance of a great rectangular barge. At the finishing slip, each floating section is completed up to full height by pouring the remainder of the concrete within complex forms, and other necessary arrangements are made to put a section in readiness for sinking. The end bulkheads of concrete will be cut through after the various sections are located in contact in the river bed trench Wherever two sections are joined, they will be bound together by an enveloping joint of concrete-the concrete being poured under water and within forms provided for that purpose. When all the sections are linked together beneath the surface of the river, then the intervening concrete bulkheads at the joints will be cut away, one by one, while the tunnel

sections are unwatered progressively Each section of the river tunnel will be handled by floating cranes and other floating equipment, and to give it deadweight to cause it to sink, it will be filled with water so that it can be lowered deliberately and precisely to its assigned location. When it settles in the trench it will rest on a temporary foundation con sisting of hydraulically controlled tacks which will hold it at its proper level. With that done, all depressions between the uneven bottom of the trench and the underside of the section will be filled compactly with sand jetted in under high pressure in accordance with a method recently devised. When all sections are firmly supported, the jacks will be withdrawn and the entire trench will be back-filled to the original level of the river bettem

To facilitate pedestrians and cyclists using the tunnel, there will be installed in a building at each side of the river four escalators, each of which will have a vertical travel of 55 77 feet. The bicycle is very extensively used in contmental Europe not only for pleasure travel but in making the daily trip, back and forth, between the home and the place of business. Hence the special provision that is being made in this under-river tunnel for cyclists, Likewise. the moderate length of the tunnel will encourage many persons to use it in walking to and from the opposite and neighboring sections of the city.

The actual building of this unusual structure is being done by a group of experienced engineers and contractors, for the time being known as Maastunnel Limited. The schief engineer for the municipality is Mr. J. P. van Bruggen, to whom we are indebted for much of our information

Figure 1: Indians mining flint at Alibates quarry From a painting by Gustaf Sundstrom

THE art of working stone into useful implements is perhaps the most ancient of human arts It dates back to the dim dawn of civilization more than 100,000 years ago, yet it is still practiced by primitive peoples in many parts of the world. One of the outstand-ing differences between man and his other relatives of the animal kingdom is his ability to make and use implements of one kind or another. Stone implements are in many in-

stances the only records that we have of early human lustory. Thus man's earliest efforts toward accomplishment are recorded in the impressionable med-

Figure 2 An accurate method of positioning and placing a blow

Figure 4: The same principle applied on a more powerful scale

rum that he has left behind-stone artifacts or "fossils of the mind." On the basis of their study the earliest phases of human history have been sub-divided. We thus speak of the Paleolithic, or the Old Stone Age, and the Neolithic, or the New Stone Age. But even prior to the Old Stone Age there must have been a time, many thousands of years ago, when man was just learning through crude efforts that stone could be roughly fashioned into a tool. Artifacts of this early beginning are referred to as Eohthic-the dawn of the Stone Age. After the stone ages came the Bronze Age, and this in turn was followed by the Iron Age.

The ancestors of the American Indians are thought to have migrated into the Western Hemisphere from Asia, in Neolithic time, following the Glacial Period. and, though their culture reached a high point of development in several localities, and though metals such as bronze

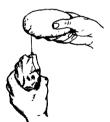

Figure 6: Practice soon teaches shape and size of detachable flake

and a few others were used, the Indian was essentially a stone-age man when America was discovered by the Euro-

In several world localities the technique of working stone reached the distinction of a fine art, due perhaps in part to an abundance of fine raw materials as well as to the character and inventiveness of the workman. One of these localities was centered in Denmark and parts of Scandinavia, one was in Egypt, a third was in the Pacific Coast region of the United States, and a fourth in the Great Plains region east of the Rocky Mountains, Here Folsom

Figure 3: The same principle ap-

Man made fine implements of stone, and with them hunted animals that are now long since extinct.

One of the largest and oldest quarries from which the American Indian obtained his flint is located on Alibates Creek, about 40 miles north of Amarillo, Texas. Here the flint is of a characteristic red and grey color with an even texture. and is easy to recognize even in a small arrow point found, as some have been, hundreds of miles from its source. Even Folsom Man, himself, who is known only from a certain definite type of implement that he made, obtained much of his material from this quarry. Figure 1, from a painting by G. T. Sundstrom. represents the Neolithic workman mining flint at the Alibates location. The writer is indebted also to Mr. Sundstrom for the other illustrations in this article.

After man passed the long, crude stages of the Eolithic Period we find him manufacturing the first definite implement of the Old Stone Age, and, though still rough in many ways, it was unquestionably designed for a useful

Figure 7: How pressure, blows, or both may be used when necessary

purpose. This early tool, known in the Old World but not in America, is called by the French a coup-de-poing, or hand ax. This did not usually exceed six inches in length, and when held firmly in the hand it probably was an effective instrument for many purposes.

The hand ax was made from a nodule of fint by striking off rough flakes until the core reached the desired shape. This technique is important and characteristic Early Paleothic time. The same technique was continued into the next epoch, but with the difference that there was a specialization toward more varied types of tools. Later, the flake itself was worked into a tool by a process known as retuching, but this was applied only to one side. The next step was an improvement and greater skill in the art of reucehing. The workman became more

proficient in the use of the awl in scaling off thin flakes of flat to achieve the desired shape and edge of the tool. Eventually we find that the enture implement was recounted. Finally, it was discovered that, by the proper application of a sharp blow from a harmer stone through the aid of an awl (Figures 2, 3, 4), flakes could be detached from the core more effectively, and that it also was possible to control the process to such an extent that long silender flakes

Figure 8: How the bone awl may be used for retouching a thin flake

Figure 9: Notched hone awl used for twisting off very small bits

Figure 10: Pressure flaking with an awl against a leather protector

Figure 11: Still another method—detaching flakes with side of awl

Figure 12: Completed, and you'll be sure your ancestor was a mechanic!

could be produced with knife-like edge, a satisfactory for use without the timeconsuming process of retouching. These steps as outlined, though apparently simple, represent nearly 100,000 years in man's advance from the Lower Paleothite through the Upper Neothic, and are so definite that chronology in culture can be based upon them.

Contrary to popular opinion the method involved in making stone knives and arrow points is not a lost art. Indeed, the the methods are rather simple, although considerable skill is necessary, and the worker will find that pannstaing practice is essential before he is able to produce a pleasing product. The only required tools for arrow making are an away, either of bone or iron, a hammer (for this purpose the Indian used a system of the stone), and a leather pad to be used as a protection for the hand from the sharpchips of flux.

THE first step in making an arrow point or a knife, or spear point is to produce a suitable flake from the material at hand such as obsidian, flint, or glass, as shown in Figures 5 and 6. This is then further worked with the hammer and awl to the rough outline in Figure 7. Now that the flake has been worked to the approximate shape of the desired implement the next step is the process of retouching In this the flake is held firmly in the hand (Figures 8, 9, 10, 11) in such a way that, by application of pressure from the point of the awl, thin scales of flint can be chipped from the edges over the surface of the flake toward the mid-line of the flake. Thus the flake is sharpened and thinned down to the desired shape, as shown in Figure 12. After the point is thus brought gradually into shape the notches for attachment are worked into the flint in the same way. First efforts will probably be crude and of the Old Stone Age type, but continued practice should bring the new craftsman with his ancient art up to the Neolithic period in which his work will be admired by others and a source of pride to himself. His respect for ancient man is likely to expand.

Lining up an Eastman removable whipstocknote slant groove-before lowering into well

BY drilling deliberately crooked oil wells instead of straight ones, a young Oklahoman has added immeasurably to the dwindling oil resources of the world. H. John Eastman, though told by engineers that it couldn't be done, showed them how drilling on curve and sant can outwit geology, put a subternaean cork in wild and flaming wells, and, by angling out under the ocean, open up to mais use huge new reserves of petroleum, hutherto counted as beyond his power to exploit.

But Fastman's methods have also opened a gusher of legal controversy. If our can be pumped from under no-man's land, the sea, who owns it 2 "We do," say, in a confusing chorus, the operators who finance the drilling, the sovereign states in whose coastal waters, it is done, and the Navy Department, speaking for Uncle Sam. Furrous controversy and legislation the ahead Meanwhile, several a states have boldly "annexed" miles out into the ahoal waters of their shores.

This new method-which Eastman calls "Controlled Directional Drilling"offers to the oil industry dazzling vistas and undreamed of skills By making holes straight, slanting, or curving at will, drillers can follow geologic formations, avoid rock structures, go through faults and under salt domes. From one derrick and top hole a driller can probe under 20 acres. This new slant-hole drilling makes available deposits formerly withheld from man and greatly cheapens and makes more thorough the exploitation of known fields. Because of its underground surveying system, well operators for the first time know where their bottoms are; and, in new fields, can plan spacing and drainage in the oil sand, instead of blundering at it from the surface.

More Oil from

By UPTON CLOSE

Where oil is found under cities, buildings, parks, and centeries, Eastman's process can tunnel down at an angle from far enough away to make unnecessary such projects as putting the dericks on the lawn of Oklahoma's state capitol Most sensational of results. John Eastman has given the oil industry its first conclusive means of controlling wild wells and extinguishing dangerous and shockingly wasteful burning craters.

Thanks to Eastman, we can get some of that 70-odd percent of the oil formerly left in the earth when wells were ribrough." The driller can start from any point along his casing, plug up the borehow that point and at small expensedril slantwise right through the casing pipe to a point at which the oil sand still contains enough pressure to make the oil flew. Or he can even turn a hole to run within and parallel to the oil beard ring stratum and drain the sand by grav-

Map showing wanderings of an oil well, from surface (0) to full depth

ity. Vast low-production deposits hitherto commercially unworkable, and exhausted fields, such as those in Pennsylvania and West Virginia, may now contribute the "fluid of Infe" for man's productive and destructive activities.

Great economies can be achieved through the Eastman method by drilling multiple holes from the same derrick. Where oil lies under shoal water the advantages of this method are enromous. At Elwood, California, piers running out 2000 feet from shore beat traveling derricks which have bored wells eight feet six inches apart on the surface and several hundred feet apart at the bottom. This field, too expensive to exploit by previous methods, has yielded 54 million harrels.

Oil men wondered how Eastman would get straight steel casing into bent holes. Eastman had been so busy he had overlooked this problem. To the surprise of all, the pipe easily bent to follow the curving hole. Natural pressure and heat helped at several thousand feet down.

Untold petroleum resources, hitherto quarded from man by the ocean, now he open to his use Much of the world's untapped ocean oil can be reached by angling out from shore. Where ocean floors shelve gradually enough to make piers or artificial islands possible, multiple curving wells drilled on Eastman principles can tap more of it. All along the shallow coast of Texas and southern California, where oil men once saw only fathom soundings, they now see dollar signs "Directional drilling" makes profitable the building of small islands many miles out in the Gulf of Mexico. It sug gests that many years can be added to the life of the world's oil resources by exploitation in the shoal waters of the Black Sea, the Caspian, the Persian Gulf, and Maracaibo, Venezuela's great inland sea, American oil geologists, according to whose past estimates we ran out of oil in 1924, in 1928, and again in 1932, will once more have to revise their predictions

POR 5000 years, ever since the Chinese began drilling for salt with stone bits hung on hamboo ropes, men have been trying to drill holes straight. Even in America's modern oil industry this has been so nearly impossible that oil men still call a well "straight" if it is less than three degrees from the perpendicular And a three-degree deviation is enough to make a 6000-foot well find bottom anywhere within an area of seven

Short piers support rigs for drilling out under water along oil strata

CROOKED WELLS

Controlled Directional Drilling . . . Significant Advance . . . Adds to Available Oil . . . Offshore Pools Tapped From Land Rigs... Other Uses

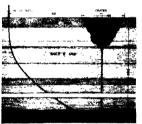

acres, often drifting onto a neighboring lease or missing the oil sands entirely Wells have been so crooked as to require 800 feet more drilling-at \$10 a footthan was necessary to reach the bottom level, others, though scientifically spaced 200 yards apart at the surface, practically met at the bottom. Charts of capricious corkscrew wells often look more like the wanderings of a mole under the lawn

Some 10 years ago, at Signal Hill, that black Golgotha of derricks at Long Beach, California, hundreds of wells driven within each other's shadows were tangling as they went down, and owners were at law over subterranean trespass Nearby, at Huntington Beach, men were trying frantically with costly piers and artificial islands to tan the oil which lay deep under the sea, Young John East man, a salesman turned oil field "roughneck" by the depression, fresh from Oklahoma and unhampered by knowl edge of engineering, worked after hours on devices to make perpendicular holes To do this, he had first to make an instrument that would trace where holes were going; and, second, a tool to correct them to the perpendicular. With these devices. Eastman made it possible for the first time for an operator to tell exactly where his hole was at every foot of depth and to steer the new well constantly while it was being bored.

Steps in turning a drill hole with a knuckle joint. After the turn-out is made, the hole is reamed until large enough for regular drill bits

Then came his simple, brilliant idea. contributed to an old profession, as so often happens, by a complete novice Why be content with correcting error's Why not pierce through the ceiling of perfection into a new field? Why not apply the technique of drilling straight holes to the drilling of intentionally crooked ones --holes which would feel their way along the slant of strata, and detour around projections of hard rock!

How Alexander I, 5000 feet deep, was killed by drilling a relief well. Explanation in text

Perhaps he could even angle out under the sea and reach those rich oil sands beyond the farthest Huntington piers!

Eastman and his young wife organized a company, put every cent into development of his tools, went broke twice in the first two years. He gathered inventive young engineers and helped them to get patents in their own names. Controversies arose--at one time he had 14 lawsuits over patents on his hands. It was tough sledding. But in 1932 he and his associates were able to set up a derrick on Huntington Beach and offer proof to a skeptical oil industry. Curving from the beach 4000 feet down and out under the sea, the well brought in more than a thousand barrels a day. One of the big California operators, the Wilshire Company, grasped the idea and took a chance, Result: A 5000-barrel well The rush was on. Ninety wells had curved away from Huntington Beach before the city and state authorities moved to bring order out

The relief well employed in killing a wild must be located a considerable distance a

of chaos and claim shares in this bounty from under the Pacific

Two years later, a still more spectacular use of Eastman's methods took him out of Califorma and "sold" his system to the oil industry in general. This was the conquest of Texas' most feared 'wild well," early in January, 1934. In the Conroe field near Houston. Texas, a well, known as Alexander I, had blown up from a subterrancan gas explosion. Its derrick was demolished and the explosion formed a huge crater nearly 200 feet across and nearly as deep, boiling with oil and throwing

off fumes as dangerous as dynamite. The entire Conroe oil field, one of the world's largest, was imperiled. In addition, the Humble Oil Company, owners of the adjacent leases, saw then wells failing while this one spewed forth 9000 barrels a day, which past experience showed could end only with exhaustion or conflagration

A Humble official had heard of Eastman's directional drilling at Huntington Beach, Eastman was called in told that if he could hit within 50 feet of Alexander's bottom the flow could be checked Was that asking too much? 'I'll go to within 25 feet," promised Eastman, "and if I don't, you needn't pay." Humble's own people would drill. Eastman would boss. That settled, Humble made a strange deal with Alexander's owners It paid them \$300,000 for the privilege of trying to kill Alexander, If the attempt succeeded, the 15-acre lease on which Alexander stood should be Humble's. If it failed, Humble would get nothing. If

First came the most elaborate use of fire protection technique in drilling history. A barbed wire barrier unequalled in no-man's land was built to keep sparkmaking men and animals out of the area. A battery of six boilers set at a distance sprayed steam continuously over the crater. Tanks of chemicals were ready to be turned into the steam to blanket the gas and oil lake with foam in a few seconds. Then a steel fire-shield was erected 400-odd feet from the crater's edge, the derrick put up behind it, and drilling begun. No one had bothered to chart Alexander with the new Eastman instrument as it was bored, and it was impossible now to put a cylinder down the erupting crater. Eastman surveyed neighboring wells and risked reputation, career, and money on the likelihood of the drift being similar.

CHECKING every hundred feet with his directional camera instrument telescribed below; Rastman hegan to shoot at his small invasible target a mile underground. He drilled straight down for 1500 feet, thin on a carefully calculated ordscrew slant, When, eight weeks later, a mile deep, he figured he was within six feet of the bull's-eye, water under 1800 pounds pressure was pumped into the slant hole he was drilling. The falling of pressure showed that the water had been forced through into the bottom of Alexander I. Within 24 hours the oil of Alexander I. Within 25 hours the oil

well stopped flowing. It had been corked from the bottom with the weight of the column of water.

Tastman was "made" yet so impersonal are oil men that today the name stands for a method, not a man. Several oil men have told me that no such man as Eastman existed! Controlled drivetunal drilling, said they, was the general property of the profession. So it is! H. John Eastman presented it in detail at the World Petroleum Congress in Paris in June, 1937.

Eastman has since done greater salvaging marvels than killing Alexander In January, 1935, he killed a burning crater for Sinclair in southwest Texas, boring 400 feet from the flame and ending within five feet of the hole

The top illustration shows drillers starting a survey instrument into a well. This complicated device, which the author explains, is shown in section at the fift, while below is the "watch-face" table on which he instrument indicates the location of the drill hole at a given depth hole at a given depth

at a depth of 2300 feet. The dol well was sealed with concrete, the oil was pumped up through the new. In Aug. ust, 1936, he extinguished a lurring well at Sibbee, Tres. as, the most spectacular conquest of a faming "hell" in history. He struck its bore at 7000 feet depth from a surface point 800 feet from the fire. His process killed a fired well in Venezuela. He "relieved" a blown well in Roumania, making his only recorded semif-silure—his

relef vent was below the source of presure. In most of these cases, he had to contend with failure of original drillers to survey their wells. But drillers are converted now. Recording of a well's position at every hundred feet of drill-pipe paid out is routine. The Supreme Court of California has established the legal autority of Eastman's surveying method.

He and his associates are supervising tobs and instruments in the greatest oil fields of North America, the East Indies, Venezuela, the Argentine, Roumania Persian Gulf, Australia, and Japan. One of his prospective jobs is turning the Black Sea into an oil field—as soon as rwal empires settle the control of that region

The basis of his method is accurate knowledge of where the bit is at each hundred feet of depth, and ability to change its course. Eastman began with the primitive method, then current in the oil fields, of hanging a partly filled glass bottle of acid down the well and leaving it for 15 minutes. The acid etched a mark along the fluid's top, showing the approximate slant of the bore But it was also necessary to check the slant against true north in order to locate the well's position upon a survey chart. South African diamond miners had dangled gelatin floated compasses down their exploration wells Eastman and several young collaborators worked to combine these two ideas At first they used an ordinary compass and fine pendulums to maintain a horizontal surface against which the angle of the casing could be photographed. Later they substituted a gyroscopic compass, which maintains true horizontal and true north undeflected by magnetized ores, lost tools, or easing pipe. This was found to be too large for best efficiency.

THE instrument that informs Eastman today is complicated, and amazingly intelligent. It can be seen at the Petroleum Industries exhibit at the New York World's Fair-a long, thin metal cylinder which contains electric batteries, a compass, a plumb bob, and a miniature camera loaded with graph film or 16mm movie strip. Sealed against mud. and let down into the narrow darkness of a well, this device will photograph, either in single shots or at repeated intervals, the position of the compass and the angle of the wall of the well. These were the eyes that enabled Eastman to see his slanting way down to within five feet of the bottom of the flaming well at Silsbee, Texas.

All this must be encased in a mudtight cylinder small enough to follow a drill bit. This watch-like instrument has actually been put in a 3.5 centimeter diameter. Its length varies from five to seven feet. Eastman is trying to make it yet more spindling. Although not a professional mathematician, he has worked out little "watch face" trigonometrical graphs in the form of negatives upon which the miniature camera photographs, at one exposure, the shadow of the compass needle and an angle shadow. The driller needs no technical knowledge; a tank develops the negative and he reads the indicated graph figures and checks the result on his blue print. About 30 minutes suffices for the entire operation of dropping, raising, and reading the instrument. (Still another survey method developed by Eastman checks by the turns of the drill pipe.)

So much for the underground survey instrument. Compared with it, the tool to guide the boring bit is simple indeed. When Eastman developed it for keeping bores perpendicular, he called it the "correctional whipstock," Now it is called the "removable directional whipstock" It is a three- to ten-foot-long hard steel shield looking somewhat like a grooved banana, fatter at the bottom than at the top, and ending with a sharp point The point-at the end of perhaps several thousand feet of drill pipe -is jabbed into the bottom of the hole. The whipstock is hung around a drill pipe by a collar just above the bit and is lowered and fixed in position at the angle desired. Then the drill pipe slides down through the collar, the bit follows the slanting groove and is deflected off through one side of the hole. As soon as the slant bore is long enough to guide the bit forward without help, the bit is drawn up, catches the whipstock by the collar and lifts it to the surface where it is detached until the surveying instrument shows that it is needed again for the next deflection

A second tool for bias drilling has since been developed by Eastman and his associates: the "knuckle-jonit," which is just a drill bit operated by universal gears and looking like a giant dentist's drill. Before lowering, it can be set to start boring at a given angle. Eastman's preference is still the whipstock,

PAMILIARITY and skill are, of course, the secrets of the successful use of these instruments. You have to know how they behave in different strata and at different angles. You must know that up to a certain speed of revolution the bit drifts right, and beyond that it drifts left, and that it tups and pierces at a right angle through hard, alanting strata—unless the slant is too great when, on the contrary, it slips along it and leads off in the other direction. And there are a thousand other tricks.

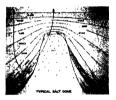

Before Eastman came along, no state or nation had much reason to be concerned with submarine oil rights. But his discoveries have produced controversy and melodrama which are national now, will perhaps be international tomorrow.

Soon after the California gold rush, a community of Spiritualias settled on the Californian coast south of Santa Barbara, and named their haven "Summerland"—their word for the world after death, for Paradiae. Their placid beach was occasionally solled by oil seepage, recognized by members from Pennsylvania where petroleum exploitation had begun. Scruples about tampering with Mother Earth were eventually overcome through the assurance of friendly octoplasma. "Spiris" guided file enterprise of the com-

munity's Colonel Wayne Darling in putting the first oil well in the world through ocean water in 1896.

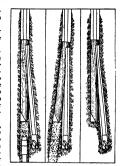

It, and succeeding wells, out as far as 1000 feet from tide mark, became as 1000 feet from tide mark, became tractions than as 1000 feet from tide mark, became profits were small. After the turn of the century, hard-boiled "black gold" propertors took the munds of Summerlanders off the other world and destroyed the character of the community. Wideatters exist upon the under same from the control of the community wideatters and applied it in the rich fields farther down the coast at Huntington and El-wood

Then came Eastman, at Long Beach, pioneering with his curves out under the ocean floor The local politicians, who had thought no more of oil under the sea than of gold on the moon, became excited over wells put out into the harbor from Ford's and Standard Oil's waterfront fills. The city had granted the waterfront sites for factory and dock space -not for oil wells. This case is still in the courts Next, the California State Senate. led by Culbert L. Olson, accused corporations of taking untold wealth from state domain without benefit to the people. Two-hundred-odd wells are drawing oil for 80 corporations from under six miles of the state's 1000 mile coastline. The wells have cost twenty million dol-

lars, and have paid the state eight million in royalties.

California drew these royalties from underwater wells, claiming the ocean oil fields as state domain. Oh no, suddenly said the United States Navy, in the person of its Inspector of Petroleum Reserves. Commander William J. Greenman. How can corporation, municipality, or state claim ownership of the sea and what lies under it beyond low tide? All this is "open territory," belonging neither to state nor corporation, but to any power able to annex it. And only the United States can "annex"-individual states cannot. So the Navy, in deadly earnest because naval oil reserves on the West Coast are inadequate, for strategic reasons supports the Hobbs Bill, which would declare these submarine oil lands to be the property of the United States

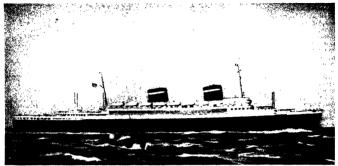

and, therefore, subject to the Navy's ad-

But corporation lawyers and chambers of commerce object bitterly. So does Texas because, alone of the states, it entered the Union not as a territory but as a sovereign nation. The Legislature of Louisiana, a tough state with the richest off-shore oil shelf of all, has already "annexed" as far out as 27 miles. Little Delaware, thinking of sea-water chemicals, has annexed out to 14 miles. Answering California's clarion call, state's righters have gone trooping to Washington with a cohort of harbor-masters in the van. The battle cry they shout is this: "If the Federal Government can preempt oil lands under the sea, by the same token it can possess or abolish the works and jurisdiction of every state or jointly controlled port authority in the union. a fantastic and also serious tangle-and also further proof of the profound significance of John Eastman's discoveries to a world that, for war or peace, cannot live without oil.

To be ready for transatlantic service in the spring of 1940, the America is the most important unit thus far in the United States Government's program for the construction of 500 American merchant ships in the next ten years, or 50 per year

WE BUILD MORE SHIPS

PASSAGE by Congress of the Merchant Marine Act of 1936 and of the amendments thereto, in 1938, evidences the determination of Congress to continue the policy adopted in the Shipping Act of 1916 and in the Merchant Marine Acts of 1920 and 1923 to carry a substantial percentage of our goods in foreign trade in our own ships, and to build up and maintain a merchant marine for both our foreign and domestic trade adequate for our national security and for our economic self-sufficiency.

The preamble to the Merchant Marme Act of 1936 varies somewhat from that in the Acts of earlier years by specifying that we should carry a substantial portion of our water-bonn foreign commerce in our own shaps whereas the previous Acts mandated that we should carry the greater part. The Act of 1936 provides for a direct subsidy to the steamship operator both in the building and operation of ships as against an indirect system in the Act of 1928.

The new Act requires that the Maritime Commission created under it should make a thorough survey to determine what additions and replacements of vessels are required to carry forward the national policy of the Act, and to study, perfect, and adopt a long-range program or replacements and additions to the American merchant marine; and, in the event that such additions are not provided by private operators, the Commission is directed to complete its longThe American Merchant Marine Begins Extensive, Orderly Expansion...Important for Our Economic Self-Sufficiency and National Security

By H. GERRISH SMITH

President, National Council of American Shipbuilders

range program by the construction of vessels for its own account for charter, and ultimate sale if possible, to private interests.

The purpose of the Act is evidently to foster the development of American shipping under private ownership and operation if practicable, but it is quite clear that its purpose in any event is to develop an American merchant marine whether this can be done through private ownership and operation or not. A reading of the Act should convince anyone of the many difficulties involved in the development of American shapping under private operation, but the Act has not yet been sufficiently long in operation to determine what the final outcome may

A BRIEF study of our present-day with the exception of the few vessels built under the provisions of the Merchant Marine Act of 1928, the vessels in our general passenger- and cargo-carrying trade are mostly wartime-built wartime-built

and have, therefore, reached the age of obsolescence It will show further that, in the foreign carrying trade, the United States is faced with the mevitable decision of putting new ships into our foreign trade services or of very soon withdrawing from these services altogether.

It is true that the foreign trade of the United States is far less than it was in the boom years of 1928 and 1929, but as value for 1938 was still appreximately \$5.000,000,00, and it will undoubtedly continue to be of such volume as to be an important factor in our economic prosperity. Its preservation and development still require a substantial participation in its carriage in our own ships.

At the present time, less than 30 percent of our commodities in foreign waterborne trade is carried in vessels under the American flag, while the percentage of the carriage abroad of the American traveling public in our own vessels is about the same.

The Maritime Commission has heeded the mandate in the Act of 1936 to provide for a replacement program so that new vessels are now off the drawing boards and are under construction in the private shipyards of the United States. Sixty-six scagoing vessels are building, 46 of them for Maritime Commission account and 20 for private owners. In this group are 40 vessels for the carriage of cargo; 13 of the combination type for the carriage of both passengers and cargo; one of the passenger type to supplement the Manhattan and I ashington now in transatlantic service: and 12 high-speed vessels for the carriage of oil All of these vessels are designed to meet the requirements of auxiliaries for national defense. The passenger vessel, to be named the America, is the largest commercial vessel ever constructed in the United States and should be ready for service in 1940

It is gratifying to know that the greater part of those vessels building for Maritime Commission account have already been allocated to existing privately operated, foreign-trade services to take the place of obsolescent vessels

A PROBLEM of great importance, which has not yet been definitely solved and may require further amendments to the Act of 1936 is the disposition of old vessels now in service when new vessels take their place in operation. It is important that such vessels, when the removed, should not be allowed to enter into competition with either subsidized government. Hence or other established services. Legislation to cover this matter is now under consideration by Congress.

The present program of the Maritum Commission, as frequently stated, is the construction of approximately 50 vessels a year over a period of years to tax care of necessary replacements. Such a program must have in mind wessels for both the foreign and the domestic trade. The Act of 1936 without some modification, however, does not offer much encouragement for the building of oceangoing vessels for the domestic trade.

As a result of the combined national defense program and the program of the Maritime Commission, the shippards of the United States are busy, in fact with a greater volume of construction at the present time than in any previous period of shipbuilding in the United States except during the World War. The 66 vessels now building under the Merchant Marine Act of 1936 involve an expenditure of approximately \$185,-000,000, sufficient to give an average ennual employment to approximately 50,000 American workmen over a period of two years, in which employment the shipyards and the various interests throughout the country that furnish materials and equipment share about

Notwithstanding shippard activity, there is no immediate need of any expansion of shipbuilding facilities other

Looking down on the hull of the America. Divided by 14 watertight bulkheads this ship has been called "the safest ship in the world" by Admiral Emory S. Land

than such expansion as may take place in existing operating shippards.

Much has been said recently, not only in this country but abroad, of the high cost of ships. It is true that the price of ships, like the price of other commodities, has risen materially in recent years, but the reasons are many and are easily seen.

Ship design of today is far different from what it was 20 years ago—or even ten years ago. The development of the art has brought about changes which have added to cost. Added requirements of owners for the greater expedition and sace handling of cargo and for the comfort of passengers have added to cost. Government safety requirements have been greatly increased with large additions to cost. The cost of labor is much higher than a few years ago, and the costs of materials, which reflect the higher labor rates, are also much higher. All of these added costs are almost wholly beyond the control of the shipbutder.

American shipping in foreign trade is in competition with the shipping of other nations whose costs to build and costs to operate are less than those of American ships, and in domestic trade it is in competition with railroads, trucks, busses, pipe-lines, airplanes, and other means of transportation; and its development is faced with many difficult problems Yet notwithstanding the problems when the problems in the problems in

PREHISTORIC AIRFOILS

THE development of the boomerang by Australan aborgues marked one of the most brilliant achievements which illuminated the dun acons of paleolitha cavilization. Those primeral tribes, of unknown linguistic affinities, foresaw and put into practical service what the advanced intellects of the 20th Century are so laboriously reclusivering; the conception and application of mechanical flight, Pertunent, too, is the fact that they developed their discovery primarily for purposes of warfare, the principles of flight again are being so applied today, threatening modern civilization with annihalation.

Like many scientific du-coveries which have proved to be really momentous, that of the boomerang was probably fortunous; perhaps the outcome of idle contemplation of the graceful gratuors of an acacia leaf or the whirling of the winged fruit of the gunt tree. Whatever it was, we must concede the presence of a remarkable mental trast within those savage minds which leapt far beyond contemplation by producing from the wood of those trees a unique and deadly flying weapon.

Even in the incipient stages of tribal life, weapons of defense and offense were a necessity. There would be times when the hated enemy stood beyond the reach of thrust or parry; when the possession of a missile filled the frenzied warrior with delight. He took chances and hurled. It was then that he made his great discoveries. Some implements flew prodigious distances-far beyond the range of a round object of the same weight. Some flew straight; some curled in their flight in curious ways. Why, he did not know; but we must at least assume that he would practice strenuously in times of peace, prizing and reproducing in every detail those implements which behaved in the way he wished.

It is likely that his very crudeness of workmanship was his talisman. Soon he would notice that all implements which were of any use were more rounded on one side than on the other. But this was not the whole secret, The weapon had to be hurled in a special way so that during its flight the more rounded side always came uppermost. This was the key to the prolonged flight. The pressure above the rounded surface was less than that under the flatter surface below. Gravity was, in part at least, compensated. The savage had unwittingly discovered the principle of the cambered airfoil-a principle of aerodynamics to

Aboriginal Boomerangs Were Based on Principles

be rediscovered untold centuries later Important as this discovery was, many uzzling problems remained to be solved. For example, those weapons which were straight, like spears, would not fly nearly as well as those which were bent near the middle-scimitar-like. In fact, Captain Cook, when he first saw boomerangs at Botany Bay, thought they were crude wooden swords. Unless the implement is bent in this way the subsequent flight is erratic and unstable. A very wide variation in the angle between the arms is permissible; from 90 to 140 degrees. In this recession of the arms we see the stabilizing principle which has been adopted in a variety of successful tailless airplanes; the backward sweep of the wings taking the place of the tailplane.

THE most remarkable feature of effective boomerang throwing lies in the skill of the thrower. The implement is thrown in a horizontal direction with as high a linear velocity as possible. At the instant of release, it is given as high a spin as possible, the implement revolving about its center of gravity O, Figures 1 and 2.

Boomerangs may be conveniently

divided into two general classes known as the Return Type and the Non-Return Type. The first is commonly used in hunting, for bringing down birds, and so on; the second is used purely as a warwaspon. In the return type the arms BA and BC are twisted about two degrees in a right-handed direction. The monreturn type has an opposite and usually smaller twist. Upon this difference of twist and the method of projection depend the characteristic flights of the two types.

Whether in the most primitive of implements such twists were intentionally made is not known. More probably they were accidental insertions due to crude workmenhip or they may have resulted through warping in the sun's heat. All efforts to find the true origin of the twist have proved abortive and it seems most probable that its influence was derived entirely from observational experience. The fact remains, however, that its presence introduces us to that all important feature of mechanical flight known as the twisted-artifol or air-acceve. In the linear propulsive and rotary motions of a skilfully hurded boomerang we have all the essentials, except adjustable controls, common to the helicopter-airplase.

When throwing the return-type implement, it is grasped by the right hand at A and held over and to the rear of the right shoulder, the plane ABC, Figures 1 and 2, being vertical and the rounded side facing the thrower. At the instant of projection the implement proceeds with velocity U in the horizontal direction OX and rotates with spin S. about the axis OZ which is also horizontal and at right angles to OX. We are at once confronted with the problem of a wind-mill airfoil projected in an oblique wind. The tip C has a maximum velocity $U + rS_1$ away from the thrower; the tip A a velocity rSr-U toward the thrower. where r = BA or BC. As a result, differ ential pressures are set up by both twist and rounding which cause the principal plane of the implement ABC to rotate about OX The direction of this induced spin depends partly on the twist, which, as Figures 1 and 2 show, acts in a clockwise direction as seen by the thrower, and partly on the rounding which acts in an anti-clockwise direction In all effective, that is, useful, specimens of the return type, the resultant of these spins, S., is clockwise and small, so that the plane of rotation ABC is seen by the thrower to heel slowly over to the right Immediately the plane ABC leaves the vertical, the force of gravity begins to contribute to the clockwise rotation through the torque of the component Mg $\cos \theta$ acting about the center of oscillation at some point O', Figure 2

IN addition, the spinning become rang behaves like a free gyroscope and, as such, each of the force- just namedwhich arise from the twist, the rounding, and gravity—causes the plane ABC to precess about the axis OY with a new induced spin. That part due to the twist is negative, that to the rounding positive, and that due to gravity negative For all effective return-type implements, these component spins are such that their resultant, S, in Figures 1 and 2, is positive and small Thus, as the boomerang flies away, it is seen to heel over slowly to the right and at the same time curl gently around to the left. This combination of induced spins S, and S2, since the rounded side is kept uppermost, results in the implement's "skying" or soaring as it

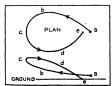

Figure 3: The simple loop flight of a boomerang thrown from point a

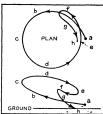

Figure 4 Double loop path of a

serves to the left. The evaluation of these angular velocities explains the character of the simple loop-flight illustrated in Figure 3. The curling to the left, due to the precession spin S_a is shown in the plain by the are above where a is the thrower and c the end of the flight. The sacrang is shown in the region be of the elevation of the flight path. The axis of mutal spin, S_a is horizontal at a. It clumbs upwards on the thrower's left and at a it is noticing unward and backward at a it is noticing unward and backward.

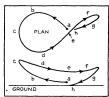

Figure 5 Another double loop, this time in the form of a figure eight

If the implement is to describe a second loop, it must be thrown much harder so that on returning over the thrower's head it has still appreciable linear velocity and spin. What will happen now depends on the position of the uxis of the original spin, S1. If this is inclined forward of the thrower, the implement will start to describe a second loop like the first, eigh in Figure 4. If it points backward above the thrower, the implement will proceed to describe a reverse loop behind the thrower, and may, if its energy is sufficient, complete the figure of eight shown in Figure 5. If the energy expires during the flight, the implement will fall gracefully to earth under the influence

of gravity.

Still more complicated flight-paths are possible as a result of an expert's skill. There is on record an authentic description of a flight involving five complete loops before the implement glided steeply and gracefully to earth.

In the non-return type, the war-weapon, the twist is in the opposite direction to that in the return type. It is hurled differently, At the instant of projection, the plane of rotation is inclined to the horizontal at an angle θ of from 30 to 60 degrees and the direction of projection is a few degrees "uphill" to the forward horizontal OX. There is but a small torque about OX when the implement has reached a horizontal position with its rounded face uppermost. If the implement passes this position, the gravitytorque falls off (since it is proportional to $\cos \theta$) and the torques due to rounding and negative twist bring it back to the horizontal which is its stable position of flight. This very small value of S, necessarily means that the precessional spin S is very small and this is especially true if S. is large, since the precessional spin

Figure 6 Plan and elevation of flight of non-return boomerang type

is inversely proportional to the initial -pin S, about OX The flight-path of this type of boomerang is shown in Figure 6. At first the implement swerves slightly to the right along ab, and returns to a point on the straight at c. Then it swerves slightly toward the left from c to d and returns again at e This sinuous path results from precessional forces which oscillate about the horizontal position of stable flight. Since the rounded face of the implement is uppermost, the downward trend of the flight path is countercted and the trajectory appears practically horizontal, as viewed in side elevation, until the forward velocity is almost spent, when the implement falls, -pinning, to earth. Along such a path, the flight of the boomerang simulates closely that of the helicopter-airplane, the horizontal plane of rotation of the arms resulting in a vertical lift which adds to the levitation arising from the camber of the upper rounded surface of the arms.

Near the end of the flight, the steep angle of glide, without the slightest suggestion of stalling, is fascinating to watch. The boomerang illustrates well those principles of mechanical flight which the modern aeronautical engineer is striving to perfect, safe descent at very steep angles combined with almost negligible landing speed. And yet the possibilities of such heavier-than-air machine-models though we may call them-were known and used in instruments of sport. livelihood, and protection not only among the primeval races of Australia, but among the savage prehistoric tribes of Central India, Ethiopia, and among the Hopis of Arizona.

A MONTHLY DIGEST

Unique Hinged Swing Spans on Bridge

THE completion of a runforced concrete Tarch bridge across Big Greek. 40 miles sould of Carrell, California, constituted the last link in a series of structures, inseparable elements of Coast Highway Route 56, hetween Monterey and San Sumoni fis construction introduced unusual problems in bridge design.

At the site of the crossing Big Creek meanders along the bottom of a deep "[1" shaped canyon. Foundation exploration in dicated that the steep, sloped canyon wallsconsisted of a badly fractured shale formation and that underlying the stream were

of Aeronautics, New York University

6 inch span with 34-foot 6-inch swing spanswhich vault the canyon walls to the abut ments at highway grade. The structure from abutiment to abutiment has a total over-all length of 587 feet and provides a clear roadway width of 24 feet.

A unique feature of this structure in volves the function of the swing spans which are hinged to the half arches boundation conditions at the bridge risk indicated that the design should anti-pate settlement of the end abutments. This condition, should it occur, may be readily overcome by virtue of the lunges which permit tacking the swing spans, back to grado without detriment to the half are best fire effect, any settlement at the abutments is localized and the correction, effected with a minimum of expendition.

The half arch spans supporting the codof the swing spans are lunged at the lower end and held in position by means of a site it yelsar be extraining from cross no crosson of the half arches. Hunguing of the half arches at their bases was indicated to elim mate stresses which would be induced by clongation and contraction of the eveluation from temperature change. If F. Ruphal, in California, Hukmayes and Publis, Works

heds of clas, sand, and gravel of reasonable bearing value for the bridge foundations. The highway alignment at this location is immediately adjacent to the sea coast and approximately 90 feet above the bed of the stream.

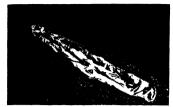

In selecting a structure most suitable for this sete, foundation conditions were of course an important consideration, as was also the locale with 1st heavy fogs, rains, and saltspray laden winds. In fact, the latter on selectation ruled against a type of construction suitable for an inland site. Full considciation of these factors led to the adoption of the reinforced concrete arch as the most suitable type for this location.

The arch structure comprises two main arch spans 177 feet 6 inches long across the canyon, and two tied half arches of 81-foot

TEN-MAN PNEUMATIC. LIFE RAFT

RECENTLY under test at Wright Field, Dayton, Ohio, has been a pneumatic life raft, developed for use with large arr planes of the hombardment type when engaged in over-water flight. When inflated and placed in the water, the raft is capable of seating 10 men, while a life line attached to the raft and extending around it will support 10 additional persons.

The pneumatic life raft ready for inflation and, right, the raft in use

The supporting structure of this raft consists of a later turber bladder with a heavy substanced duck outer cover. The bottom is of heavy rubberzed duck fabric and contains three pneumatic inflatable seats. The later tubes are equipped with valves and dislaters tubes are equipped with valves and manifolds for CO, in required for the inflation operation. The cylinders containing the tool operation. The cylinders containing the manifolds for CO, are statered for the inflation operation. The cylinders containing the united to the raft and red directly mited the tubes. The weight of the raft when on inflated is approximately 115 pounds. When folded the raft can be rolled into a bundle approximating three cubic feet of space.

Four two-section metal oars make propel ling of the raft possible in the water for a considerable distance Four army cantenso of water, a quantity of emergency rations, emergency signal kit with six red flares, and a pyrotechnic pistol form additional equipment All of these are eneased in water proof holiders.

In order to repair possible punctures while afloat, an emergency pump is provided. With a repair kit, this makes it possible to keep the rait afloat indefinitely. When inflated, the buoyancy is such that the raft is virtually nonsinkable. It will float even if turned upside down on the water, and has been found to be considerably more stable and more easily handled than the smaller size.

more easily handled than the smaller sizes.

In the bombardment airplane, the rafts will be stowed in a position within easy reach of personnel

Experimental testing at Wright Field having been completed, an order was placed for

CATALYTIC REFINING

CILIANTE de la company de la c

As currently operated, catalytic refining plants produce about 45 percent of 80 octane gasoline the first time the crude oil is passed through the stills, making no fuel oil unless desired, and producing only gasoline, gas, gas oil, and a small amount of heavier residue. On subsequent runs through the stills, additional amounts of gasoline and other

usable products are obtained. Conversion of 100 percent of the crude oil into gasoline is physically possible under the new technique.

Catalyte refining adds the action of a catalyst to the action of a catalyst to the action of heat and pressure, the physical contact of the oil with the catalyst causing a chemical reaction which converts greater portions of the oil into gasoline. Refinery gases, resulting from cracking and distillation, also are subjected to catalytic processing, adding still further yields of gasoline.

or gasonie

A BLIGHT-RESISTANT CHESTNUT

SEVERAL years ago the Bureau of Plant Introduction of the UV Department of Agriculture Brought in shipments of the Chinese cloestini Castonia mollivium ain an offort to find a variety that would be resistant to the cloestial thight which worked such havee in the cloestial trace of the United States that practically every American chestinal has been destroyed Crowso of one or more of these chestiauts were sent to the Bartlat Tires Rewards Inducation's,

Blight resistant

for 20 years and has fruited for several years. The not, 100, 30 similar to that of the American chestnut in szee, quality, and severenses. Mr. Bartlett carly recognized its merits and lass distributed more than a thousand ont-year-old seedlings to commercial nut growers in different sections of the United States. Because of the service rendered by Mr. Bartlett in cooperating with felleral agencies the chestnut has been named by government workers, the Bartlett chestnut.

In some instances, our native chestnuts have sprouted for a few years, and some have vern fruited but then succumbed to the blight so that it does not appear likely that a doseas-restant native chestnut will grow again in the areas originally affected by the blight—E. F. Greeves/d appear

Instrument for

CHEMICAL ANALYSIS

BASED on established principles and developed by the engineers of the Fisher

D veloped by the engineers of the Fisher Scientific Company, a new instrument has been announced for conducting qualitative and quantitative analyses in both organic and morganic industry.

The Electropode, as the compact instruction count is called, employs the droping mercury electrode system for analysis. With this yakem, a series of potentials are applied to drops of mercury as they fall through the solution being analyzed. The results are plotted and the presence of each particular on is undexed by an increase in the current at a specific voltage. The extent of the increase depends upon the ion concentration.

Another View of German Aviation

WE have heard glowing reports of German avaiton from many sources, and German hombors have been Huler's tump card in his diplomatic or, rather, undiplomatic maneuvers. Is it just possible that the Reich's strength in the air is over-rated? Picture Post, a well informed English magazine, published some interesting views in this regard.

One hundred pilots a month were killed last year in the German Air Force, which is an indication of hurried training, and of weakness rather than strength.

Visitors have apparently free access to German airplane factories and are duly impressed with such facts as the production of three-engined bombers at the rate of nine a day, or single-scater fighters at the rate

Exterior of the pressure tunnel for testing airfoils and airplane models

of twelve a day But such glimpses may be deliberately misleading. Picture Post says "That factory may have been building its airplane parts for months, and other parts may have been worked on by other facto and all might have been ready for the final assembly of aircraft the day before the visitor was shown over " The final rapid assembly might thus well be the culmination of months of relatively slow effort.

Again, in building American Pratt & Whitney engines under license, the quality of the steel was so bad that the crankshaft of the engine had to be strengthened, weight of the engine increased, and over-all efficiency lowered. It is also reported that the German-built Pratt & Whitney Wasps have to be overhauled every 35 hours, whereas in the United States overhaul is placed in hundreds of hours, German airplane tires made of synthetic rubber have a life of only 40 hours, which is but a fraction of the time that American tires will serve

These are rumora Still there is some resson to believe that reliability may have been sacrificed to quantity in the Nazi Air Forces. and in time of war, only that airplane counts which is capable of continued service.—A. K

MULTIPLE HANGARS

FROM time to time we have pointed out in these columns that hangar space is valuable and that hangar rent is an important item in the budget of the private plane owner. Considering the present type of conventional hangar, elaborately constructed in steel and concrete, with high roof trusses, it is obvious that hangars cost money, and that the present high rents are probably a necessity. To overcome this drawback, the Edwards Multiple Hangar has been designed to reduce the cost of airplane housing, and also to provide the owner of an "airplane garage" with housing of such flexibility that he can adjust his space to current require-ments and not be tempted to speculate by erecting an expensive building which may remain half empty.

One of our illustrations shows a sevenunit hangar block. The low over-all height, made possible by use of a special cantilever russ, is only 16 feet as compared with the 36-foot height of the conventional big hangars. This reduces the minimum area required for the landing field, since the approaches become lower. The staggering and overlapping of the hangars reduce the ground required for a number of machines

to the absolute minimum. Each unit house a single plane. The hangers can be built singly, or in blocks of two or more as de sired. The privacy of each block should make an appeal to the amateur flier -A K

A HUGE PRESSURE TUNNEL

OF great interest to visitors at Langles Field is the 19-foot pressure tunne shown in one of our photographs. To secure conditions comparable with those of flight. the new 19-foot tunnel is designed to use air at a pressure of two atmospheres, the speed of the 19-foot diameter jet will be 250 miles an hour In operating the tunnel, the operators will work inside the pressure chamber. like the "sand hogs" who drive tunnels under our rivers. Special air locks and a decomion chamber will be provided

The tunnel is of steel tubular construction with a maximum diameter of 60 feet, a length of 270 feet, and a width of 128 feet The 34% foot propeller will be driven by an 8000horsepower electric motor In the working ber the large forces on airful or airplane model will be recorded by automatic balances, which will give the engineers a faithful picture of what they may expect from the actual flying machine -A. K.

"SMOKED" GLASSES

THE American public has declared a de-fensive war on invisible rays, using for armor certain types of glass which protect the eyes by admitting visible light and stopping the invisible ultra-violet and infra-red rays. A 700 percent increase in the use of this glass since 1928, amounting to many tons, is reported by the American Optical Company.

According to latest scientific investiga-

tion, the invisible ultra-violet and infra-red rays are not necessary for seeing and in excess quantities may produce pathologic eye conditions. The protective glasses, the composition of which is responsible for their absorptive qualities, are used for outdoor wear to protect the eyes from excess light (glare of the sun) and the invisible rays.

Many years of research were required to develop efficient absorption glasses, Dr. E. D. Tillyer, the optical company's research director, stated The problem was complicated from the beginning by the difficulty of cutting out the invisible rays and maintaining at the same time a desirable transmis-sion of the visible light rays.

Finally, after long experimentation, certain elements in pure form having ultra-violet and infra-red absorptive properties were discovered. Added to batches of glass, these elements produced glasses which transmitted light without undesirable color distortion and at the same time uniformly absorbed the invisible rays.

The elements having these remarkable properties, Dr Tillyer stated, were cerium (a rare metal resembling iron but much softer) and very carefully balanced quanti ties of iron compounds. To prevent color values from being distorted, he emphasized. the ratio of the iron compounds must be watched very carefully

CONQUERING THE ATLANTIC

T is now a matter of record that Pan IT is now a matter of record their American Airways have crowned their many achievements by the first scheduled flights across the Atlantic, under commercial conditions of operation. All honor to Pan American and to the Boeing Clipper (See also page 76, this issue.) The achievement is all the more remarkable when we consider how brief is the chronology of transatlantic service. Scarcely twelve years ago (October 1927) the first international airmail and passenger service extending beyond the borders of the United States was established by Aeromarine on a little 90mile airline between Key West, Florida, and Havana, Cuba. Early in 1929 Pan American Airways formulated its first plans for transatlantic operation, undertook a complete survey, and adopted specifications for aircraft, weather and radio services, base facilities, and so on. In 1931, the first "laboratory were made on a northern great circle route. In 1932 and 1933 there were expeditions to Greenland, and the building of the Sikorsky S-40, the first four-engined flying boat. The year 1933 saw another survey head ed by Colonel Charles A. Lindbergh. In 1935 was held the first international conference on Atlantic air travel. Then came more surve a larger Sikorsky, and finally, in 1938, the Yankee Clipper was constructed. Then cam shake-down flights, more surveys, and, finally,

Multiple hangars for airplanes conserve space

in May 1939, the first regularly scheduled flight. To the public the establishment of this service has seemed slow. In reality, progress has been very rapid, when one considers the immensity of the task.

Pan American will not be left alone in the transatlantic field. We may expect Air-France, Imperial Airways, Lufthansa all to be active. And, moreover, there will be an other American company in the field Thus American Export Airlines has filed with the Civil Aeronautics Authority application for a certificate of convenience and necessity covering Atlantic routes from New York or Baltimore, via Botwood, Newfoundland, to Foynes, Ireland, Horta, Azores, Biscarrosse and Marseilles, France. As soon as the latest Consolidated flying boat, shown in one of our photographs, has been approved by the Authority, three survey flights will be made. one of these being non-stop from New York to Biscarrosse A strong argument in the application is the fact that the new airline will be affiliated with American Export lines, which maintains a fleet of 18 surface vessels. From five to eight of such ships are normally at sea at all times between New York and Gibralian With complete two way radio and meteorological observation services, the help to navigators will be immense. In vestment bankers have bought enough stock to finance the venture on a sound basis

The Consolidated Model 31 Flying Boat has made successful test flights with 52 passengers and a crew of five. The Model 31 is a twin-engined flying boat, powered with Duplex-Cyclones of 2000 horsepower each The gross weight is approximately 50,000 pounds Hydraulically operated Fowler flaps extend from the hull to the ailerons. The rear portion of the hull is so designed that the tail surfaces rise high above the water, and the vertical surfaces project well below the stabilizer, which is a safeguard against spin. There will be two full decks Wing -pan is 110 feet (arrying 28 passengers, the boat will be capable of non-stop commercial service across the Atlantic.

Pan American with Boeing Clippers, against American Export with Consolidated Model 31, will provide the competitive zest which is needed to secure maximum effort and efficiency on the part of both companies. -A. K

No-SLIP PAINT

FROM United Laboratories comes announcement of a new non-skid paint for use on stair treads, concrete floors, steel floor plates, and other places where resistance to abrasive action is desired. It is known as Armor Plate 419, made up of stainless steel flakes in varnish vehicle - Streamlining

MOST POWERFUL AIR-

COOLED ENGINE

BUILT by Wright Aeronautical Corpora-tion, and known as the Duplex-Cyclone, the most powerful air-cooled engine in the world is of the radial type with 18 cylinders arranged in two rows of nine each, and is rated at 2000 horsepower. It derives from the Double-Row Cyclone of 14 cylinders which is rated at only 1500 horsepower. Provided always that a suitable propeller can be designed to absorb its immense power ef-ficiently, this latest engine will do a great deal to increase the speed both of our trans-

ARTIFICIAL HEART

REMARKABLE artificial heart which A can replace any animal heart for pumping blood at its ordinary temperature of degrees, Fuhrenheit, through the arteries and veins has recently been perfected by Dr. Gerhard Katz, of Tulane University, This heart can, in fact, be used either for the perfusion of living organs with fluids other than blood, or for the maintenance of the circulation of an experimental animal. It can be operated at a maximum speed of 100 strokes a minute, although a lower rate is usually preferable. An air valve in the heart is opened and closed by a photo-electric cell activated by two brams from two light sources, which pass through the glass tube and are interrupted by the blood column. These light beams are focused by lenses in such manner that one passes through the bottom of the tube, while the other one is focused on it at any desired height

During the systole operation, the air valve is opened and the top light is dark. Air pressure then pumps the blood out of the tube into an experimental artery, for example, until the blood column reaches the beam of the bottom light. This beam is thus al-

Above: The artificial heart perfected by Dr. Katz. Below: A closeup view of the mechanism used for research on experimental animals

lowed to penetrate the glass tube and activates the photo cell, which then closes the air valve and switches on the top light. The output of blood per strike is regulated by the height at which the top light-beam passes through the glass tube Increase or decrease in the venous blood return to the heart correspondingly changes the ordinary rate of flow.

This artificial heart his been used in studing the action of arteries, weins, and kalanys, when detached from the animal to which they originally belonged. An outstanding advantage is that it can be showed down which, me hancial. It contains neither timners are the studies and the studies of the means are the studies and the studies of the means are the studies and the studies of the means are the studies and the studies of the means that the studies are not to the studies of the studies are studies because the blood which comes in contact with them sometimes becomes tour. NEW SMALLPOX VACCINE

On the heels of news of recent smallpox outbreaks in New York and Tennesse comes an aunouncement to scientists of a new smallpox vaccine which eliminates this severe scars and other inconvenient features of ordinary vaccination.

The new saccine was developed by Dis Thomas M Rivers and R D Bard and S. M Ward of the Hospital of the Rockefeller Institute for Medical Risearch in New York It is made by growing vacine virus on a special midium consisting of minered chickentity of time and Tyrode's solution. Vaccinations against smallpox ordinarily are made with call lymph vacine virus.

Vaccination with the new vaccine virus should be followed, within six months to one

year, by re-saccination with ealf lymph virus, the Rockefeller scientists advise in their report to the Journal of Experimental Medicine. "In this way," they state, "saccinated individuals will not become sick and will not be subjected to the dangers associated with primary vaccination with ealf lymph virus, but will obtain a solid and lasting imministy to smallpox."

No sear forms after the primary vaccination with the new accene virus, it is reported, if the moralation is properly mad-Nor is there any fever or discomfort. Following revacemation later with call lymph virus, view few of the children had fever or other symptoms, and what sears or curred were only "small superficial" ones. Science Service.

ANTI-CORROSION

An aqueous solution of alcohol is one of the commonest antifreeze solutions for automobiles. The addition of less than I percent to weight of mirate salts, according to a recent patent, will present corrosion of aluminum parts of cooling systems.

IT "TALKS BACK" TO YOU

THE machine shown in one of our illustrations can both 'listen and 'talk back.' And it's a perfect minne too In fact that's its job. It "mirrors" what is said to it --sends it back as a curately as a mirror reflects your image.

Looking like little more than an endlessel of narrow seel tapes wound upon small drums, this device is a your executing and reproducing machine that has many uses. One of the first of its kind was introduced several years ago as the "tome merror," and thousands of visitors to "open houses" conducted by the telephone company in New York State and elsewhere used it to "hear telephone transmitter, and then heard the exact words and tones spoken back to him through the receiver.

Applied to everyday use, such devices pro-

Spray painting over a floor grating; no booth is necessary

vide the "voice" for the telephone company's weather forecast bureau in New York City, and in New Jersey are used to give farmers and produce dealers crop reports by telephone

In recording the voice, a moving belt of steel tape passes across the poles of an electro-magnet at a rate of about a food a second white speech currents produce a varying magnetism on the tape. The machine will repeat the message indifinity. The recording can be "erassed" by the fisck of a key, and the machine is the ready to take a new message.

SPRAY PAINTING WITHOUT BOOTHS

UNIQUE facilities for spray painting which climinate painting booths remove the fire hazard, and make it practical y impossible for operators to inhale the spray, have just been installed in the lattle manufacturing plant of the Monarch Ma

chine Tool Company.

I athes are now being painted on the assimbly floor within a few feet of other operations with no walls or partitions of any kind to screen off the sprayers. Painting is done over a seven by twelve foot grating in the

floor through which are is shausted at the rate of 200 feet per munter. The fune-laden are is discharged into a large welded tank located directly look whe grating where a continuous case adv. of chemically-treated water effectively suggested to the paint funes. This presentates a yogong sowart of the presentation of the paint funes. This presentates a vogong sosumently by classed from the pit. The are is then carried off through an underground numel to an ourside exhaust state.

Since the solids precipitated in the water are non-inflammable, the fire hazard created by the highly combustible pyroxylin which collects around the conventional spray booth, on the floor and in the exhaust system, is slummated.

With the air suction down instead of up, and since the painter never has to hold the spray gun above his head, which would put him between the spray gun and the exhaust the operator is niver in a position where he can inhale the funnes. The draft is strong enough to pull effectively into the exhaust any spray not immediately deposited on the notal bring paint d.

FOR POLISHED PARTS

APPLIED by brush or spray gun, No-Rust Lquid V-15, recently introduced by Frost Paint & Oil Corporation, dries quickly to form a tough, non-porous film which resists abrasion, the clements, and sait water, and is recommended as protection for polished steel parts in storage or shipment. It is readily removed by wiping with k-rosenor gasoline—Streamlang.

VITAMIN ALPHABET GOING OUT OF STYLE

THE sitamin alphabet, that is, designation I of the various vitamins by letter, is going out of style For example, if you want to be really up-to-date, you must learn to say accorbic acid instead of vitamin C when you are referring to the substance in orange juice for other etrus fruits, tomatoes, and other vegetables) which prevents and cures service.

This may be discouraging, especially if you pride yourself on having really learned the vitamin alphabet, or most of it. But the scientists who have most to say about vita-

Steel tapes and recording and reproducing mechanism of the "back-talker"

mins- the nutritionists and biochemists-are trying their best to get the vitamins out of the alphabet They make the point that the letters did very well for names in the early days of vitamin discoveries when only a few were known and not much was known about them. Now, however, since there are about as many vitamins as letters of the alphabet. with half-a-dozen going under the name of B, it is confusing and even leads to maccuracy to call these essential food factors by letter.

Some of the vitamins have been identified chemically and even made synthetically They have regular names, just as othchemicals have. Vitamin C is ascorbic acid Thiamin is the beribers preventing and curing substance that once went under the e of vrtamin B or B. Nicotinic acid, the stuff that is curing pellagra, is the chemical that was variously called vitamin B2, vita-min G and the P-P or pellagra preventing factor Riboflavin is another diet-essential that was once labelled vitamin B or vitamin G Recent discoveries have shown that it is necessary for the health of both man and other animals

The anti-sterility vitamin, formerly called E, is now known as alpha tocopherol Vitamins A and D may keep their letter names for some time, because there is not so much confusion about them as about the B vitamins Until the chemical composition of other vitamins is discovered, however, scientists favor calling them by descriptive names, not by letters -- Science Service

NEW AUTO SPRING RELIES ON RUBBER

DEVELOPMENT of a new type of automobile spring which uses three pounds of rubber and seven pounds of steel in place of the usual all-steel construction was an-nounced recently by the B. F. Goodrich Company The new spring requires no lu-brication and reduces rattles and squeaks. reports Science Service.

Rubber springs have been invented and patented many times, but none has ever come into general use. The new spring gets around the difficulties of most of its predecessors

Above: Rubber springs in the front-end of a motor car. Below: One of the springs, showing how rubber is placed between a shaft and a shell and stressed in torsion

through the fact that the rubber is under ession and twisting or torsion pressure instead of being under stretch or tension When under tension, cracks develop in the surface of rubber and it soon deteriorates

The rubber surrounds a central steel shaft and is in turn surrounded by a pair of hemispherical steel shells. By making the rubber layer a little larger in diameter than the inside diameter of the steel shells before they are fastened together, the rubber is put under pressure High pressures are applied during the curing process to bond the rul ber and metal firmly. The spring is stressed in torsion by anchoring either shell or shaft to chassis and rotating the other member.

The entire arrangement takes advantage of one of rubber's most marked and most desirable characteristics, its ability to absorb and damp vibration This has not previously been done in the springs in widest use in automobiles

NEW PLYWOOD FINISHES

TO extend the usefulness of plywood further in modern building construction. 1 F Laucks, Inc., has presented two important new paints that offer not only decoration but fire resistance as well to plywood construction

These two new paints are known by their trade-names, Rezitex for certified exterior plywood, and Plasterez for interior plywoo walls. They have as their binder a special combination of synthetic resins, which as sures perfect adhesion to the plywood, and a surface that is durable and non-brittle. Both paints are heavy bodied and will cover up small cracks and joints in the plywood

These products were originally developed for application on plywood, but since have proved themselves suitable for application on all types of surfaces—plaster, wood, metal, and wallboard. Rezitex and Plasterez both simulate plaster, stucco, or concrete finish

HOOVER DAM

N newspapers recently there has been considerable comment regarding the question of the name of the dam recently completed in the Black Canyon of the Colorado River Officially named "Hoover Dam" some yearago, its designation was changed to "Boulder Dam" about the year 1933 It now appears that this change was never officially made for in an exchange of official correspondence recently, the United States Attorney General indicated that the name "Hoover Dam" had been legally fixed and that it was not frasible to change it Since new maps will carry the original designation, Scientific American will henceforth refer to this proset as Houser Dam

BACTERIA AND MINE FIRES

MINE fire is sometimes extinguished A by blocking off and scaling the area To determine whether or not the fire is out, tests for carbon monoxide are made of the -caled atmosphere

Recent studies by the U S Bureau of Mines have shown that, under favorable conditions, unidentified bacteria or micro-organisms which inhabit waters and sludges of anthracite mines react with carbon monoxide and produce carbon dioxide. These studies show that failure to find CO in a sealed area does not prove the absence of fire as barteris may consume the gas as fast as it is produced by the fire

PROGRESS NOTE--

TRAFFIC CHANGES. 1904 to 1937 BRITISH automobile traffic appears to be

moving backwards A survey of traffic speeds by Great Britain's minister of health reveals that in 1904. the average speed of a horse-drawn bus traveling from Swiss Cottage to Oxford Circus, in the heart of London, a distance of about four miles, was not quite nine miles an hour. In 1937, several tests indicated an average

speed for the same journey by motorbus of out eight and a half miles an hour. In 1904, the average speed on a trip from Highbury to Piccadilly, about five miles, was a little more than eight miles an hour. Today, the speed is somewhat under eight miles an hour .- Science Service.

LONDON PLANE TREES

ONDON plane trees, among the few species that can stand the smoky air and other unfavorable conditions of city life, are now menaced by a killing epidemic are now menaced by a kining epitemic disease, the U. S. Department of Agriculture recently reported. Seven thousand of the trees are dead in the Philadelphia region, and 700 in Baltimore. The disease has also appeared in Washington.

The infestation is a slow killer. In the

first year, cankers appear in the bark of the trunk and large limbs and dark streaks in the young wood. In the second year the leaves thin out. The tree may die then, or linger one or more years longer.

The London plane is a cross between the American and European plane trees or systemores. It is widely used as a shade tree along streets and in downtown parks because of its hardness under cuty conditions. Its disappearance would denude many American cuty streets and leave cuty foresters and park commissioners at a loss to find an equally good substitute.

R. Kent Beattre, Department of Agriculture plant pathologist, is seeking information regarding the distribution of sick London plane trees. It is requested that chips of young wood from planes or vycamores suspected of having the disease be sent to the Division of Forest Pathology, U. S. Department of Agriculture—Science Service.

WATERPROOF FABRIC

ZELAN is a recently announced watertrepellent finish for fabrics. Developed by duPont, it is claimed that the new finish is the first which will still shed water after the merchandise has been washed or dry cleaned many times.

Other water-repellent finishes coat fibers like wax on a thread, and some of the waterproofing chemicals cover the entire cloth and close the pores of the material, making the garment hot and uncomfortable to wear

Instead of coating the fibers, it is said that Zelan goes into each individual fiber. It be comes part of the material itself without closing or clogging the pores, thus the cloth can "hreathe" and the garments are much more comfortable to wear.

AN UNFORESEEN RESULT OF AIR CONDITIONING

WHEN an air-conditioning unit was installed in one of Boston's large yeavily stores the primary consideration was the comfort of customers and clerks. It was soon wident that there was a more practical ben-fit from the ansallation. The humidity contol and the removal of sulfur from the air by the air-washer clumnated a source of silter trainish, and it was found that ailver articles on display had to be potashed much less frequently.

THE CULTURE OF ORGANS

AT the instant of a human being's legal A death, and for hours and ometimes even days thereafter, major sections of the body are still aliev. Consciousness and many brain cells may be dead, yet at the same time the beart tissues as well as smany another tissue may often be found living, merely in a low state of activity. Delt technique frequently can induce an apparently lifebes heart to truch. These facts have long been established, but little has been made of them until recently.

Now new methods yield important discoveries. The hearts of dead patients can be revived and kept beating for hours, within the body or cut out. In such revival, blood or a bloodlike synthetic fluid is supplied to the heart and its vessels through a double set of tubes. From one reservoir, fluid at high Pressures is forced through these piercing the

A FAIR WITHIN A FAIR

by Westinghouse

It has taken a World's Fair to make us realize all over again that ours is not a commonplace business. More than 12 months ago we undertook the task of erecting our own building at the New York World's Fair. Today there has sprung up a treasure house of wonders devised by the inventive minds of an organization trained to think in terms of practical applications rather than spectacular showmanship.

Instead of an ordinary cornerstone laying, we buried the Time Capsule with its significant message of our times for people who will live 5000 years from now.

In our laboratory we discovered that everyday experimental equipment could be transformed into headline attractions for a Playground of Science where visitors crowd the aisles to see the shape of their own voices, transmit music over a beam of light, and demonstrate to themselves other mysteries of science.

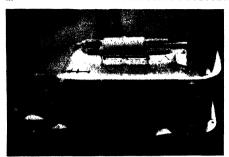

An engineer's dream was brought to fulfillment in the form of a friendly Frankenstein who walks and talks, counts on his fingers and distinguishes colors to the delight and amazement of crowds who throug his every appearance.

Our auditorium cannot accommodate the audiences who stand in line to witness the triumph of modern woman over drudgery, as accomplished by one of our lesser-known appliances.

To add to the enchantment of the Fair as a whole, as well as our own building, Westinghouse engineers took advantage of the latest developments in illumination, hydraulics and control devices to create the Singing Tower of Light with its breath-taking symphony of music, water and light.

Behind the scenes, Westinghouse has collaborated with the Fair and other exhibitors in making possible all the wonders of this World of Tomorrow. We furnished the lighting and power equipment for the spectacular Lagoon of Nations where thousands of fair-goers stand nightly in awed wonder. The longest electric stairway in the country, the exterior lighting of the Perisphere, the production of Florida climate on Long Island, are examples of a few of our transportation, lighting and air conditioning contributions to this greatest of all fairs.

It is gratifying to realize that our own people were able to take a World's Fair in their stride and handle it as they would any ordinary, everyday job. We hope you will visit our building and spend time enough with us to catch the spirit of Westinghouse which we have tried to interpret to you in our exhibits.

sorts and passing directly and the heart's private circulator, system, the commany vesses, From a second reservoir which develops a lower pressure, fluid is made to flow less forcefully through another tube, that goes forcefully through another tube, that goes the valves of the sorts and not the ventrale. By this method, hearts can be perfused and kept in thybino contraction for as long as four hours. These are human hearts—which had stopped all action at death. Hearts of experimental animals can be kept alive much longer.

The Carrel-Lindbergh techniques inducts the advent of methods which should give in-definite life to organs in glassware. They should nether age nor the, awa Carrel of organs in such culture of the future. Today organs in culture may show no great change after weeks And there is sready advance in the preparation of choice notirent fluid or in the pump which forces the fluid under precise pressures into the blood vessels of the organ outside the body Carrel has devised new bases for the whole research; Lindbergh a more practical pump.—From "Low" by Barclay Moon Newman.

WALL PAPER REMOVAL

A PRODUCT developed for use by paper Annagers and decreases the tendency of water to form droplets by lowering the surface tension. Thus, when one ounce of the powder is added to one gallon of water, the solution will wet old wall paper almost instantly and permit its removal more readily.

SOUNDPROOF PORTABLE DIESEL GENERATING PLANT

EYERROWS went up early this apring when Paul Gross drove has larest creation, an ultra-modern soundproof, portable, Dereel electric generating plant onto the Schmick International Studio lot in Holly-wood, Grosso's striking looking "Paran child" was built from a re-vamped cab-over-engine truck chasses entirely of Durla and at a cost of \$24,000. Entirely portable, the new sound-proof generating plant makes it possible to get within 200 feet of a movie set on location without disturbing the sensitive sound microphones. An ordinary generating set must be at least 1000 feet away with a need

Above: The soundproof truck, with muffler and oil radiator on the roof. Below The truck driver's seat can be reversed so that the operator faces the convenient controls of the Diesel-powered generator

for less than one fourth the cable, transmission line losses of the high amperage direct current are greatly reduced. Grosso says he can work as close to a set as 100 feet with a building or some sort of a deflector between the generator and the microphones.

Crosso has found a way of balancing the speed of his Diesel with the amperage loads, something electrical engineers have been trying to do for years. Any variation in the engine's speed, large or small, does not affect the voltage output which has been predetermined and set by the master control knob This is of tremendous importance to the movie industry, especially now that Technicolor is gaining in popularity. It is well known that color movies demand a great deal more light than black and white movies Any variation in the line voltages tends to change the intensity of the artificial light which, in turn, causes the hue of the photographed color to change. As the light decreases, many colors fail to register and all tend more toward the blues.

Total thickness of the walls enclosing the plant is three inches, made in three separate "layers," with a one-inch, sound deadening, are space between each. On sold metal where sound-proofing was desired, a militure of cork and rubber was built up with a spray gun to the proper thickness. The floor is made up of \$\frac{3}{2}\$, such five-ply wood one inch of the cork and rubber compound, and an-inch the wood All free edges are sealed and the top is covered with linoleum Windows are made of a sheet of transpar

Windows are made of a sheet of transpar ent, synthetic glass on the outside, and two sheets of plate glass with one inch air spaces between on the inside. The outside of the truck body is solid Dural riveted and bolted

SULFANILAMIDE TREATMENT

THE new drug, sulfandamide, has extended its sphere of usefulness to cover out is media, that extremely painful disease of the middle ear that often is the forerunner of a mastoid operation.

Eighty-eight patients with otitis media due to heta hemolytic streptoeccus were given sulfanilamide in a recent series of cases and only seven required a mastoid operation, reports Dr Gibert E Fisher of Baltimore in the Journal of the American Medical Association.

In a control group of 95 patients who were given the regular treatment of puncturing the membrane for drainage and irrigation, 66 required a mastoid operation

Moreover, the patients treated with sulfanilamide recovered in one third the time taken by the other group—Science Service

DRY ICE AIDS WELDING OPERATION

IN the construction of a 40 foot welded susted to prevent the high temperature from bucking the steel plates. Four cakes of dry cewer used, two inside and two outside the hull. The cakes were placed as close as possible to the weld while the plates were being joined, and it is reported that the resulting flat surfaces are fully satisfactory.

COLORING CONCRETE

FLOORS

ACK of permanene and lack of resultance to mousture and alkali are two baggers that to mousture and alkali are two baggers that the state of control of the state of the state

A new system, called the Truscon Flor-Dye System, developed by the Truscon Laboratories, may be used on old and well-matured floors. The only limiting condition is that the floors must be dry at the time of application. This is called a "system" because it consists of two materials: (1) Flor-Dye, a penetrant which stains, seels the porces, and helps hind the priciles at the surface; and (2) Flor-Dye Dressing, which protects the Flor-Dye and affords a polish or sheen to the surface. In some cases, Flor-Dve may penetrate a mere 1/32 of an inch and in others it may penetrate as much as by inch. Because it does penetrate the concrote, the concrete still takes the wear

Both materials come in four standard colors-tile red, Spanish green, light brown, and maroon-and both materials should be used as a complete system on any floor color ing job. The system is not affected by mois ture or alkali in the concrete. It is acid-proof. oil proof, non-staining but not gasoline proof It cannot be applied over paint, varnish, or lacquer. Such materials must first be completely removed

SIMPLE TOINT LOCK

WHEREVER any two solid materials are joined, a new device will find application and in many cases will do a better job of joining. This new device is the Homes Spline Lock, which those who have investigated it believe will find many uses in industry it supplants expensive tongue and groose connections, dowels, nails or screws dovetails, rabbetting, and lapping in wood working Eventually it may supplant also mits, bolts and cap screws for connecting parts of even the heaviest metal machinery

The basic simplicity of the Homer Spline Lock may be seen in the small diagram which accompanies this item. The splines (or keys) are inserted in the matched grooves of blocks A and B in an angular relationship to each other. The result is that

Above: Two blocks are firmly joined together by means of a simple pair of keys or splines inserted in the positions shown in the lower part of the drawing. Below How the spline lock system may be applied to a drop forge or pile driver

Waldorf Rates Have Not Increased!

THE WORLD'S MOST EXTENSIVELY AIR-CONDITIONED HOTEL

It really doesn't cost any more to stay at the Waldorf . . . in fact, luxury and service considered, the Waldorf costs less. One of the added satisfactions of your visit to the New York World's Fair is that in choosing the Waldorf, you pay only our standard rates!

And stopping at the Waldorf is. in itself, one of the never-to-beforgotten experiences of your visit to New York.

APES NOT STUPID-

JUST HUMAN

M RS APE can learn by aping Mr. Ape but he can't learn from her as wellmost because it as difference but apparently because it is hard for a dominant anial to take leasons from a submissive one. This observation of app ways, of possible implication in education of their human relatives, was reported to the Southern Society for Philosophy and Psychology by Dr. James H. Elder, of the Yale Laboratories of Primate Biology at Orange Fars, Florida.

of Primate Biology at Orange Park, Florida.
Despite popular notions, it is quite a tirck
for an ape to crack open a stubborn eccount.
He can roll it around and fumble with it
for a long time without getting anywhere.
Only once dud Dr. Elder find a chimpanize
that could crack the nut by his own efforts;
that seemed to be a happy accident

It takes a firm hold and a sharp pound against the concrete floor to crack a coomul. After Dr. Elder had allowed his chimpanices to struggle alone until they gave up the problem, he showed them how. Two apes learned in just one demonstration. They could then show other spees how, and they can learn just as quickly from each other.

But in two cases where the spe "instructor" was demonstrating for a dominating animal, the pupils could not learn even after as many as 16 demonstrations. These two poor learners were not stupid, either; one, in particular, was very intelligent.—Science Science.

"Z" NICKEL

COMPARABLE with oil-tempered steel in strength, stiffness, and hardness; tensile strength from 2% to 4 times that of structural steel; resustance to wear equivalent to that of hardened steel—such are the claims made by the International Nickel Company for their recently announced "2" nickel wire and strip.

Being 98 percent pure nickel, the metal is rustproof and highly resistant to corrosion and oxidation. It is suited for parts which must have a high order of mechanical properties, together with corrosion resistant and rustproof properties. It is useful for springs,

spring washers, diaphragms, wire brushes, leader wire, fish hooks, camera parts, airand boats, and other parts of electrical and mechanical equipment.

Because of higher strength and stiffness.

"Z" nickel is useful for improving performance, reducing weight of parts, or both.

INCENIOUS RAZOR RUADE SHARPENER

NEW blade sharpener, with rotary honing action, hones and strong both sides of both edges of any Gillette type blade in one operation. It is a precision instrument. engineered to improve a blade edge and keep it in smooth shaving condition

Refer to the illustration. The tooth shaped hones are inclined inwardly so that the grinding surfaces of the inter-engaging grind-

Just slide the case

ing teeth together form a grinding angle corresponding to the cutting angle of the razor blade

With a blade in position on the pins and the case closed, the blade rests with equal spring pressure from all four inclined grinding surfaces for simultaneous operation on the four sides of the cutting edge. Then, sliding the case up and down the string, the eccentric pins cause the blade to force apart alternately the two sets of hones, producing a reciprocatory movement of the blade on the hone surfaces. Result a smooth edge for every shave New blades are improved by honing off the tiny metallic "fuzz" often left on them

The case of the Blade Master is smart and compact, being of durable Bakelite. The ones are made of a mild abrasive material with a binder, built to last indefinitely. The metal parts are cadmium plated and rust-

TRICHINELLA SPIRALIS

THERE seems to be a widespread misunderstanding regarding the life cycle of the trichina parasite, Trichinella spiralis. This false impression was reflected in our recent article "Animals Bring Us Diseases," in which the author wrote that those parasites ingested by the eater of pork products are the only ones to be found in the human body. The editor who handled that story unfortunately let the statement stand. We are glad, therefore, that we can give below an authoritative statement regarding the life cycle of this parasite, from the U. S. Public Health Service:

"Following the ingestion of uncooked or undercooked meat containing viable trichina larvae, the larvae are freed from the cysts by the action of the gastric juice. They then migrate from the stomach to the small in-

to maturity. The series mate within the course of a few days and the adult females begin to produce living young on or about the fifth day after infection. These young larse every promptly enter the general circulation of the host and are carried by the blood stream to all, or nearly all, of the voluntry muscles of the body. Larval production by the adult female worms continues to take place for a period of approximately six weeks following the heginning of parturition."

OIL-PROOF INDUSTRIAL

TIRE

W/ITH the rapid development and wider wises of mechanized maternal handling equipment, there has been a marked increase in the use of rubber tires on trucks and trailers used in intra-plant hauling, according to Wislon C Bray, manager of The B F. Goodrich Company truck and bustice department.

"A new industrial tire, specially compounded to resist the action of animal, vegetable, and mineral oils, to be known as 'Oil-Pruf,' is now introduced," reports

Mr Bray.

"Trees of ordinary construction, when subjected to oils, disintegrate and become four and spongy. Under such conditions, they are susceptible to rapid tread wear, cutting, and chipping. Tests varracid on for several years in steel mills and by meat packing companies prove that these new tires retain their original physical properties approach when you from the presence of oils and other solutions usually classed as rub-ber solvents.

"The 'Oil-Prul' ure should be a boon to companies operating industrial equipment over floors saturated with oils and greases. Tests actually prove that the added service to be expected omer than offsets the small additional charge necessary to cover the high cost of specula materials which give the tire unusual properties," the rubber company sales officials and,

SEEDLESS WATERMELONS

SEDLESS wateraselons have been produced by treating the unpollulated for the publishers series acid. The melons were also series acid. The series was also some, however, were normal in shape and saze. The texture of these fruits was firm and solid No difference in flavor could be detected from normally pollulated fruits. The work on these fruits is being done by Cheoneyan Wong at Michigan State College

PLASTICS FUSE "WOVEN WOOD"

PANELS made with permanently finished wood veneer, fabricated by treating skilling woren arrisp with plastice, are now available to furniture designers, interior decorators, architects, and others interested in a finishing material which combines durability with beauty. The Parkwood Corporation, in conjunction with engineers of General Electric's Plastics Department, made

the new panel material available.

The veneer is coated and impregnated with
G-E Textolite resin varnishes and a remarkable toughness is the result. After cutting

the veneer into strips of the desired width, close, accurate weaving is possible. But further treatment is necessary to fuse the woven sheets into satin-surfaced, durable panels that can be cut and worked within practical application.

In order to produce such panels, the woven sheets of impregnated wood veneer are cut to the describe sizes and are bonded to Textolate laminated material under heat and pressure. The desired tough, resilient, and smooth surfaces are the result.

The finished panels, in thicknesses of 3/54 or 0.020 inch, have a variety of applications. Mounted on ordinary plywood or other solid

Table top of woven wood

backing. Parkwood Textotic constitutes a fine new finish for such objects as drsks, dark tables, calmets, hars, walls, and cerlings. Unafficied by mosture, alcohol, fingernail polsh, and most common acids, the material is also resistant to cigarette burns. In the 0020 meh thickness, it is surprisingly fixable and can be stitched, stapped, and one unit with ordinary shears, like a piece of the lealer In cultive thickness it can be formed, cut, and applied by ordinary woodworking methods.

A panel of Parkwood Textolite, after the final treatment, has a surface almost as smooth as plass and a pattern that looks like a fine. highly polished messare Numerous-feets are available through the combination, in weaving, of various light and dark woods Panels are ordinarily made with light or dark red mahogany, avodre, a goldenshaded wood imported from the Vory Coast of Afrea, birch, either red or white, New England majele, and walnut

BACTERIA IN WATER MAINS

IT has been found that heteran multiply in hemp For this reason a rubber compound made in tubular or wedge-shaped sections is replacing jute and hemp as caulking materals for water main. Tests have shown that sterilization of hemp and jute can be accomplished, but bacterial multiplication starts again as soon as the germicidal action ceases.

NEW LIGHTWEIGHT INSULATION

A NEW product named Celotex Superlite Insulation, which should be of special interest to the refrageration field, has just been announced. If weights less than 7½ pounds per cubic foot but high insulation and sound absorption values are claimed for it. It is of board form, but is a soft, non-structural insulation. It may be fabricated, cut, or heart to moderate curvatures to fit

Evinnude so insepted and economical to operate The sense tronal new "Mare" fits your own or rent-doost-drives row-bosts up to 4½ miles an hour, canoes up to 5 miles Runs all day on a single gallon of fuel. Amazing esart ing ease — a fick of

INDUSTRIAL SLIDE RULE

THE Langsner Industrial Slide Rule, manufactured by the Eugene Dietzgen Company, is designed to solve an unusual range of industrial problems, yet in a simple way, with only one movement or setting of the

slide in the majority of cases.

The Langsner Rule was developed to the practical requirements of mechanical engineers, industrial engineers, shop men, time study experts, and machine designers. It is simple to read even for the person who is not a slide-rule expert. It is 10 inches long.

•	T		talend o	2111	unni	r.	en v	11.7	٦.	
	-	-	-	eg	122	22	7 10		-	_

٩		100	11100	2	-tim				<u>.</u>	_

engine-divided on white celluloid, with glass "frameless" indicator, and is packed in a case with book of instructions.

The Languere combines many rules in one although there is only one slide. The face has sax scales. Two of them above the slide represent feed, length of cut, and damater, three of them on the shide represent revolutions per minute, time, and cutting speed, the regular D scale is below the slide. The reverse side of the slide contains the insual B, Cl and C scales, for standard sidecrule and C scales, for standard sidecrule manifered in red, the remaining three in black, for conventione in use. The table on the back present familiar constant familiar constant

With the new slide rule, solutions to many problems are obtained at a glance, such as surface speeds, cutting speeds, diameters of cutters, drills, and so on, required resultions per minute of any work; feed ratios, length of cut, time required, time-study data, and other factors.

NICKEL FROM CHLORIDE

SOLUTION

TO replace the conventional sulfate electrolyte used in nickel plating, a processhas been developed employing a nickelchloride-boric acid solution. The new chloride bath is said to produce a deposit which is finer grained, amoother, harder, stronger, and somewhat less ductile than ordinary nickel-plating deposits.

In addition to the above advantages, a 50 percent reduction in tank voltage and power consumption is permissible; control of the bath is easier; and high sinde and cathod efficiences are attained. The plating is more readily buffed, has less susceptibility to pitting, and has less tendency to form nodular growths and trees on thick describe.

STREAMLINED TURKEYS

THE aim of certain turkey-breeding work to it to develop a small turkey to fit the modern small oven and suitable for the modern small family, according to Berley Winton, in charge of the Department of Agriculture's poultry-bushandry investigations. There is a

Industry Accepts Scientific American

—THE ONLY National Publication to show a consistent FIVE-YEAR GAIN in Advertising Linage. 20% GAIN IN 1929 OVER 1928

Dependence follows quickly upon acceptance and Scientific American, because of its exhaustive treatment of industrial research, has won the acceptance of leaders of American industry.

Not content with merely reporting the news of the frontiers of research and invention, Scientific American long ago began showing industrial leaders how to apply the new developments from those frontiers to today's procedure.

And in today's procedure, Scientific American plays a definite part. Industry depends upon this publication to bring it the guiding facts that lead to the purchase of the products advertised in Scientific American pages.

Build your sales upon this dependence. Know that your selling facts are read by the men who do the buying, in the publication that impels their buying interest.

Ask us to show you copies of the letters received from American industrial leaders seeking buying guidance from Scientific American.

Stegosaurus Sez Horse Squirrei Turtie Polar Bear Steer

Bend for our complete illustrated list SELLRIGHT GIFTWARES CORP. 826 Gates Avenue Breeklyn, N. Y. growing demand for small market turkeys, he says. The smaller turkeys out of the annual crops of the standard varieties sell at a premium of ½ to five cents a pound.

It will take probably another few years before the destrict characteristic are "fixed" in the new small-type turkey. Winton points out For that reason, the Department will distribute no hereding stock, hatching eggs, or poilts until the geneticists are satisfied that the small type turkey is "genetically pure" for small size and other desirable qualities, and able to reproduce itself true to type, in the future

The Department geneticists want to establish in the new turkcy the small size of the white Austrian variety imported from Scotland and of strains of wild turkeys from Virginia, Pennsylvania, Michigan, and Arriona They hope the new turkey will also inherit the meaty breast of the wild turkey.

To reinforce the inheritance for white rolor, the geneticias are using the white Holland in the breeding program to produce the small-type turkey. They are also counting on the white Holland—and two other domestic varieties, the bronze and the black to contribute early maturity and other desirable characteristics.

If the Department men succeed, the smalltype turkey will be white, with a compact body, short legs, a long keeb hone, and plenty of breast meat. It would mature in 24 to 26 weeks, the young hons weighing 6½ to 9 pounds dressed, and the young toms between 11 and 15½ pounds dressed.

Other goals for the new turkey are that hens kept for breeding purposes be able to produce a reasonably large number of eggs by June 1 Ninety percent or more of the eggs would be fertule and 80 percent or more of the fertule eggs would hatch

Insulation of Glass Flux and Mica Dist

IN the German electrical industry, a new insulation material, now in use, is composed of a combination of glass flux and mis a dust. It has the advantage of being extraordinarily firm, maintaining a high heat content and a minimum of dielectric current loss. This material is important in high-frequency technique and in the manufacture of electric switches.

COSMETIC TO PROTECT WORKING HANDS

A NUMBER of skin protective creams sometimes called liquid gloves—have been on the market for years. These have here used to protect the hands of workingmen against the action of various kinds of chemicals, paints, and solvents.

A new compound for this purpose, called "shelters" in and of sush pure ingredients that the manufacturers claim that it is even after out. In using this, the workman first safet which he applies a, liberal quantity of stretz when the safet which he applies a, liberal quantity of Shelliers and rubs it in until the sticky freign disappears. This one application shrelds the skin from drit, gasoline, paints, infecting disappears. PHOTOGENIC NEW YORK WORLD'S FAIR

THEX just couldn't userier the amateur. The New York World's Fair was too full of good priture material to say to plus output programs. Thus far may you go and no fairbur. As a risult, the amateur cameraman at the World's Fair may shoot anywhers, at any time, any subject he takes a fair yot for very the indoor grine shows are humed, as they are not nown. Some off the think of the programs of the programs of the programs of the programs and shoot all the pictures you want?"

But the best stuff is outdoors, and that is all to the good because there is nothing to beat sunlight for general shooting. There is one hazard in this connection however, and that is the fact of dependence on the vagaries of the weather Clouds are needed to help fill in blank areas and lend a beauty and grace to shots of the Fan buildings. In hen of clouds, for these seem always to be absent on just the day you happen to visit the Fair, a contrast filter such as the orange will go a long way by providing a dark tone to the blank sky, thus avoiding the white paper effect that is the bane of pictures which include the sky in the view Such a filter was used in making the shot of the principal illustration for this article. The crescent shadow of the Trylon cast across the

Sphere invited photographic attention but it was not until the viewpoint shown was rached that an interesting composition presented itself. Clouds seemed imperative, but the orange filter supplied a good substitute, in fact, a substitute that was very appropriate to the scene.

The Theme Center, consisting of the Pensphere and Trylon, may be seen from most sections of the Fair grounds in majestic

"Archery at the Fair"

"Pageant of Stone"

reign over all the activities within the war area. Doubless the majority of pictures taken of the Far eather include the Thome Centre within the twee or make it the sole subject of the picture. One might result asker up a whole series of short ying up some feature of the Far with a view, near or i mote, of the Thine Centre, Small stops will often be necessary, as in the case of "The Theme Centre Percades All." but small stops are easy at the Far, where the preence of so many light-toned holdings under a vast sky makes small stops or very short expourse a necessity, particularly if you

use the new fast films in order to take care of indoor situations and the possibilities to come at might

Frequently one runs across isolated bits of sculpture such as that of the winged subject illustrated here. This was taken against the sun, with the latter positioned directly behind the base support of the subject

"Archery at the Fair" is an example of the sort of picture that will require several shots in order to make a later selection of the most interesting arrangement. In this par trular case, the three most attractive figures in the line up were chosen as the main point of footi

Night shooting at the Fair is easily as: complished with the fair films and fast lenses. Most shots will be in black and white, but you will be missing the "opportunity of a lifetime" if you do not attempt some color Exposures are relatively long but the buildings may be had at 1/10 of a second with stop //28, while other subjects, such as the color displays in the fountains, will call for responses at this stop ranging from 1/5 or 45 to 1/25. Chest or similar camera supports are in order for many camerasine the World's Fair is most attrictive at night cheefly because of the color individual single

Needless to say, a good film supply is the beta insurance against running short just when you're getting into the awing of the thing. If you plan to carry an extra camera for color, plus accessories, one of the popular combination "catch-all" zupper bags will be found handy.

Uses for Blue and U.V. Filters

ALTHOUGH little publicized as compared with the yellow, red, and green filters, the U.V. and blue filters are found useful in several different ways. The U.V., for example, is employed to cut out base when it

"The Theme Center Pervades All"

is not possible to employ other filters for the purpose because of the longer (cynsure required Fer example, if the lone is stopped down considerably and the metre asset to give 1.25 of a second, it would not be possible to use a filter unless a tripod were available for the yillow or red filter would call for a longer exposure than could safely be given to more than the condition of the contraction of the

The blue filter finds as greatest usefulness in indoor photography. When subjects has mg a far skin are photographed by artificial light on panchromate film, the results do not always show pleasing fields tones. We have found that the use of the blue filter placed over the lens greatly improves the results Another use for the blue filter is in the projection of two by two-risk color sidest was necessarily find that the same processes we occasionable find that the Shipping a blue filter over the lons has resulted in magneyment of the color values.

How Cartoon Movies

THE inside story of cartoon movie making is depicted in a Universal Idomin film, "Cationalinad Mysteries," by Lowell Thomas, now available on rental from the Bell & Howell Filmosound Library Told in complete detail is the story of the making of an Oswald Rabbit cartoon, entitled "Softhall Game."

Two film stories are spliced and mounted in the desired sequence, the "how" story first and the complete curtoon second, or the re-

E VERYONE who owns a camera has a chance of winning a valuable prize. Make plans now to enter your prints in this contest. You may enter any or all of the three divisions, but not more than two prints may be entered by one contestant in any one of the divisions.

Specific rules for this contest were published in our May number. Be sure to read them before you submit prints.

On Division 3 Action—including all types of photography in which action is the predominating feature in sach divinion there will be prize of two Longines watches—"The Worlds Most Honored Watch—and two Ped eral Enlargers, as well as five Honor able Mention Awards This Contest Clases December 1, 1939, at Which Time All Entries Must be in the Hands of the Judges.

Photograph Contest Editor, Scientific American

24 West 40th Street

New York, New York

In use, the camera is pre-focused, thereby obviating disturbance during an operation and exposures are made by a nurse stationed at a distance from the operating table. Upon order from the surgeon she presses an elec-tric push-button which trips the camera release, the camera shutter thereupon auto-matically sets itself for the next exposure. The camera is coupled to the operating room light and follows the center of illumination to any part of the table

DESIGN AGAINST THE SKY

THE extreme usefulness of the reflex THE extreme useruiness of a camera under particular circumstances was demonstrated the other day when, strolling in the park, we gazed upward and saw outlined against the sky the beautifully curv-

"Design Against the Sky"

ing branches reproduced here. The peculiar formation was directly overhead, and, with the reflex camera we happened to be carrythe camera so that the lens was pointing directly upward, while we observed and composed the subject at eye-level position without straining the neck

SHOOTING AFTER A DAMP NIGHT

AMATEURS sometimes complain of un-sharpness appearing in one picture while the very next exposure seems to be perfectly satisfactory. This may be due to any one of a number of causes but one of the reasons not ordinarily realized is that when a loaded camera has been exposed to a night of dampness or rain, the film is inclined to warp a little, causing unevenness of surface The remedy is to waste one shot and thus get rid of the first film frame, going on to the next for the actual exposure. Or make your shot with the first frame and then follow it with another just to see what the results are.

THE DIVING CYCLIST

AT a stated hour, announced long in advance, certain "acts of daring" and so forth are performed in the amusement parks. forth are performed in the amusement parks. The picture of the diving cyclist was made at Rye Beach's Playland. A position was assumed that would include some of the spectators, and a small enough stop was used -//11 being found sufficient—to show in satisfactory sharpness both the rapidly mov-

he Diving Cyclist"

camera. The reflex miniature camera used was held high above the head with ground glass upside down and the shutter snapped as the bicycle left the runway Since it was desired to get a somewhat off-sharp image in order to retain the effect of movement, a shutter speed of only 1 100 of a second was used

THE MORNING STROLL

TUST after the hose had been played over the sidewalk, about 7 o'clock of a June morning, the sun, reaching over the city buildings, swept the stones with its smile A viewpoint was adopted by the photographer

"The Morning Stroll"

which would bring the light in his direction This afforded a better tonal effect and the shadows of subjects passing to and fro came in the diagonal direction desired. A man and a dog out for a stroll was an agreeable subject, and the picture you see is the result.

RAY-DEL PHOTO CONTEST

PHOTOGRAPHIC contest open to all photographers and not restricted to any make of camera or type of film used, is an-nounced by the manufacturers of Ray-Del Negative Developer. Because of the self-balancing characteristic of the developer featured by the manufacturers in their advertising, the sponsors require that all photographs

UNIVERSAL PHOTO ALMANAC AND MARKET GUIDE 1939

AMATEUR photographers who feel that they should be able to make money with their cameras will find in this book many hintthat will be of value. A series of articles tells what, when, and how to photograph, how to sell your otographs profitably, how to handle your equipment, what picture make contacts with editors, and many other things that the wouldhe photo journalist will want to know, A pictorial section presents foremost photographers; a large formulary gives in compact form most of the standard formulas. The market guide section tells who purchases what kind of photographs, approximately the price paid, and gives other pertinent data regard-ing hundreds of publications that are in the market for photographs.

submitted must depict the theme of balance in some way. For example, a photograph of a log-balancing himself on a narrow fence, a newborn baby heing weighed in a scale, or the balance of a sailboat turning gracefully in the wind Cash prizes will be awarded

In the wind Casa prizes with he awarded. The sponsors say "The balance idea offersman's suggestions to the photographer During the summer season, the traveling crues and the county fairs offer many opportunities for getting pictures illustrating balance. The acrobats, jugglers, and bareback riders all lend themselves to pictures explide for entry in the contest. Closing date for the contest is November 1, 1939.

By Proxy for the Sun

A STRONG reflector of light will behave in practically the same manner as the light source itself. For example, we are all familiar with the path of light cast by the sun across a body of water. In the picture reproduced here, taken from a ferriboar as

Light teffected from windows of one of the tall buildings in the background was strong enough to produce this "sun path" effect

it approached downtown New York City latone afternoon, the windows of the tall buildings all reflect the sunlight, but in one or two places, this effect was particularly strong. In those places the result was a glare, and the long "beam" cast upon the water is very similar to that which the sun itself would have east from the same position.

PROOF OF THE PUDDING

WHEN it's your "yes" against the other man's "no," let the picture decide the issue At least that is the way one deterowner who had found that the foot scale on his outfit did not check with the ground glass, came with his complaint to the camera importer There the repair man told him that he had checked the camera and found it to be O.K. The customer had his doubts He set up his camera on a tripod and used for subjects a number of books set on end. the tacket cover side facing the camera. The books were carefully spaced, with a ruler. six inches apart, and the distance from each volume to the camera also similarly measured. A photograph of the set-up showed that whereas the scale read five feet, the book

Profitable Photography with the Miniature Camera

By Edwin C. Buybaum A.R.P.S.

BESIDES having a considerable amount of fun with the miniature camera, making trick "shots, art photographs, and the like, you can also use it for special paying work. This little paper-bound booklet of 72 pages tells not only how to make interesting photographs that are salable to news agencies or magazines but also gives many clues to the very large number of types of photographs that can be sold. For those who wish to mix profit with pleasure this booklet should prove most helpful .-- \$1 10 postpaid.

PHOTO MARKETING CORP. - Dept. SVF 10 West 33rd St. New York, N. Y. at this distance was out of focus, although the book at six feet was in perfectly sharp focus. When he brought in this "evidence he did not have to say a word. The picture told the story

PIGEONS AT REST

In the city pigeons are everywhere, most appropriately in the public parks. With the squarels and the ducks, they are con tinually being fed, and often photographed Frequently they may be seen lined up in a row, as in the illustration. An angle shot,

"Pigeons at Rest"

with the lamp offering an agreeable accent. and the few leaves in the upper left corner "filling in" for balance, brought the subject into a itasonable composition Too, the pigeons are nicely spaced so that the interest is spread across the entire length of the diagonally placed lamp-post extension

HANDY RECORD BOOK

REFERENCES to formulas, methods, and other photographic data are made easily accessible with the Redi-Record, a visible card index system available in pocket size The individual cards measure 212 by 3 inch es, a quarter such edge of each being left uncovered for the index. The card, while rather small, affords enough room for a for-mula or process, as well as flash exposure data, and so on The book may be carried about in the pocket and whenever one runs across a new formula or other information that may prove useful later either in shoot ing pictures or darkroom work, the record can be made immediately At work such a notebook can sometimes prove invaluable

BETTER GET STARTED!

ONTEST closing dates have a way of Creeping up on one in a manner that gives rise to the old expression: "Where has the time gone to?" In the case of the Fourth Annual Scientific American Photographic Contest, the closing date was purposely placed far enough in advance to enable every one to make adequate preparations for submitting their pet prints. But therein lies a possible source of difficulty. With the closing date set at December 1, 1939, there is always the chance that some amateurs are going to think that there is so much time for preparations that they will put things off until the last minute and hence fail to reap the in

BOOKS___ BOOKS Double exposure avoided because crank will not turn unfil shutter has been released and shutter cannot operate again after making an exposure until crank has been turned Shutter fully enclosed. Camera provided with folding mirror (concealed in finder hood). permitting eve-level focusing and composing. Camera includes leather carrying case. nera introduced to fill gap between Model II Rollescord and Automatic Rolleiflex.

ELECTRICAMERA (\$8.75): Is a complete box camera with an electrically operated shut ter synchronized with an Abbey Flashgon

cause the electrical shutter automatically catches the peak Electricamera allows for side lighting, remote control, and other features associated with more expensive equipment

VICTOR ADD-A-UNIT ANIMATOPHONE: 16mm motion picture and sound apparatus per mitting adding additional units as desired Starting with small basic sound projector, complete in itself, outfit of any size can be secured by adding auxiliary units. Basic prosector provides silent or sound motion picture, microphone facilities, and phonograph record amplification for average size room. Adding amplifier and another larger size speaker furnishes ample sound motion picture or public address facilities for large auditorium Broadcasts, recordings, and announcements may be relayed to as many rooms as desired when Central Radio P. A. Sound System unit is added.

Zeiss Tenax I (\$60): Makes 50 picture one by one inch on 35mm Contax daylight loading spools Features a lever that winds

both film and shutter, Exposures pos sible at rate of one per second for sequence picture-making. Equipped with Novar //3.5, 3.5cm focal length lens. Example of depth of

field afforded by this lens, when focused at 8 feet and stopped down to //16, depth of field extends from four feet to infinity. Compur shutter from 1 second to 1/300, and bulb. Fitted with large eye-level optical view finder. Rewind device provided for other than Contax spools. Exposures automatically counted. Lock prevents double exposures. Dimensions 1% by 2½ by 4½ inches; weight 10 ounces

MELLOWBEAM LIGHT DIFFUSERS (\$1.75 to \$6) : Features new "light-carrying" material Lucite. Can be supplied for all models of Victor Lighting Units. Use of Lucite in combination with Fibreglas held to be of particular value when used in color photogranot change color of light source. Claim is made that these diffusers provide good light distribution properly diffused, retaining its original characteristics under prolonged use without disintegrating or discoloring from heat or age. Exposure time recommended is twice that of undiffused light.

X-ACTO AUTOMATIC MAT CUTTER (three sizes, \$6.50, \$10.50, \$15) · Precision instrument for bevelling, cutting, scoring, empre-marking is eliminated. Device features "Mechanical Wrist," made of solid bronze and slotted at angles of 55 or 90 degrees. All metal construction.

AGEA MINIPAN New film for documentary recording. High resolving power Speed, contrast, color sensitivity, anti-halation in proper balance. Capable of resolving up to 135 lines per mm (3400 lines per inch), varying with precision of recording equipment used. Available in following units 100 and 200 foot rolls, 35mm unperforated, darkroom loading; 100 and 200 foot rolls, 35mm with single perforation, darkroom loading for Photorecord Camera-100 foot rolls. 35mm perforated or unperforated, daylight loading, with leader and trailer

SOLAR COPYING STAND (\$24.50) For use in copy work, table-topping, macrophotogra-phy, and so on Provides platform for mounting subject in perfect

focal plane with camera. Camera support affords universal adjustment of camera position, both vertically and horizontally. Camera supporting arm fully counterbalanced. Movement up or down the post controlled by oversize wheel knobs operating friction clamps

to lock all units in any desired position Vertical adjustment to 36 inches from baseboard

KINGSLEY SQUEEGER PLATE CLEANER (6-02. bottle, 30c) · For all ferrotype plates -chrome or japanned

WILLO FAVORITE EASEL (\$9.75): All-metal combination easel and paper cabinet. Easel forms cover of light-tight cabinet. Margins controlled by drawing out lever. White surface facilitates focusing and image arrangement on ease! Enlargements up to 11 by 14 inches directly on easel Cabinet permits storage of paper up to 14 by 17 inches. Ribbed rubber padding on bottom of cabinet insures against accidental skidding during enlarging.

Dr. Jur-Amsco Precision Superimposition IMAGE RANGE FINDER (\$5.50): American made, incorporating large, sharp-focusing method. Extending viewing eyepiece for rapid centering and reading of image. Focusing of lens finder by micrometer ball-bearing adjuster revolving in bronze bearing. Uniform dial markings. Moving parts of steel. May be fitted to any camera. Internal construction allows for large light area. Com-plete with sling and leather carrying case.

◆ Perfect enlargements—that's a goal more easily reached when you use a Wollensak Enlarging Velositigmat. For this superior enlarging less faithfully reproduces all that you caught on your negative. Free trial period Speeds 13.5, 14.5, 16.3, focal lengths 2" up, and mexpensive. Reg U S Pat Off

WRITE US ABBEY PHOTO CORP.

IACOB DESCHIN, conductor of our "Camera Angles" department, will ansuer in these columns questions of general interest to amateur photographers II an answer is desired by mail, incluse a stamped, addressed envelope Queries should be specific, but Mr Deschin cannot undertake to draw comparisons between manufactured products nor to advise on the purchase of equipment or materials -The Editor

O. We are obtaining equipment to take pictures in color of pathological specimens such as livers, hearts, lungs. and so on, of poultry for the purpose of projecting same on screen. All work will be done by Photoflood illumination because of the constance of the light source, Reflected light from the object will be measured by an exposure meter at 12 inches, Questions: 1. Should the object be illuminated by one Photo flood lamp directly over the center or two lamps so placed as to illuminate from the sides? Since the specimens are moist, there will be streaks or spots of intense light on them. How can these be climinated? 2. What general or specific rules would you suggest in respect to the color and type of background, and what kind of material would be suggested for the back-ground? 3. The writer has been advised that the smallest opening or higher "f" value gives the greatest detail in the picture. Is this the general rule and may the smallest opening be used? What difference would there be in the resulting picture between an object strongly illuminated at short exposure or moderately illuminated at a correspondingly longer exposure? 4. What 'tricks of the trade" are recommended for obtaining third dimensional effects? 5. On the table of film speeds we have two values are given, one for sunlight and one for tungsten. In which classification would Photoflood and Photoflash fall? 6. Is Photoflood illumination satisfactory for Kodachrome film in bringing out good color copy?-S. A. R.

A First, we must question your use of the word "constancy" in describing Photoflood light The intensity varies with use, growing weaker from one time to the next The measuring distance will depend on the size of the area being photographed Generally speaking, the measuring distance should be roughly equal to the width of the subject, that is, if the subject measures six by eight inches, hold the meter about six inches from the subject, being careful, of course, not to block the light with your hand or the meter 1 Even illumination from the sides is, in general, preferable to the use of a single light s surce. The use of diffusers over the light

our es should do the trick of cutting down the effect of strong light on moist specimens 2 Use a background of medium gray or omewhat lighter tone. The purpose of a background is to afford an area of contrasting tone to that of the subject being photographed so that the latter will stand out clearly. The material used is of no consequence It may be cardboard or felt cloth. the latter is most widely used by photographers 3 The greatest sharpness of a lens is generally about two stops smaller than full aperture but greater depth of field and more details in sharp focus are obtained by stopping down the lens considerably, even to the smallest opening. For subjects such as yours and particularly since you are photographing in color, where sharp detail is unportant, the smallest opening is to be advise l Strong illumination as compared with mod crate illumination is not entirely a matter of exposure, better tonal quality and diffusion of light into the shadows will be had with moderate lighting-and usually the reverse with strong lighting 4 The best "trick of the trade" we can think of is to use a stereo camera Short of that, we might suggest "playing" around with the lights, making one a little weaker, or moving it farther away, than the other. 5 Photoflood lighting comes under the tungsten heading Photoflash cannot be measured, exposure being governed chiefly by a table of distances available from your dealer or the manufacturer of the flash lamps you are using 6 Photoflood lighting is the most widely used type employed in color photography.

Q. Does an automatic film transport a camera to take sequence shots? If not, what does determine if camera will take sequence shots? After all the film is exposed, isn't it best to develop it right away? A friend savs it does not matter if it is developed a month or more later. Who is cor-rect? What other kinds of range finders are there besides the split image type? --J. N. B.

A It is not merely the automatic film transport that permits a camera to take the rapid sequence type of pictures you evidently have in mind, but the fact that shutter wind and film transport can be accomplished with unusual rapidity. Sequence pictures can he made with any camera having the convenience of automate film transport combined with abutter wind, the number of shots within a given period depending on the type of abutter wind and the abulty of the photographer to work the control rapidly. Special sequence cameras are available on the market giving pictures one and squarter the condition of the material with the special condition of the material with the with the very large of the control of the condition of the windows camerawhich have as an accessory a rapid film winder.

It will do no harm to delay development of a roll of film for a reasonable time, say a month or so

The coincidence type of range finder, in which two overlapping images appear, sharp focus being achieved when the two are superimposed or coincide, is the other principal type.

Q. Can you give me a rough idea of how mans four by five-inch prints can be developed in 16 ounces of metolhydrochinon developer before it has to be discarded?—C. W. G.

A I nder favorable conditions that is unhampered by such hazards as accidental transfer of hypo by the finger tips, and so forth—about 75 prints of the size you mention can be developed without change in developing time or print quality, using 16 ounces of MO di veloper.

- Q. Enclosed is a negative showing the reflection of a lighted electric sign projected onto the sky in a night view of a city landscape. Can you tell me the cause of this reflection and how it can be remedied in the final print?— I. I. K.
- A The reflection you refer to is exactly the same as that obtained when shooting directly into a light source. Internal reflection between the lens surfaces is the cause However, because of the light tone of the reflection, it will be an easy matter to spot it out if printed on non-glossy paper.
- Q. I am going to purchase a folding type camera with 4.5 lens that takes the second of the second of

A Since we are not in a position to set one camera up against another, it is not possible to gave a recommendation. However, at should not be too difficult to choose between the three cameras you mention for example, you may like the dose of having a top-speed of 1-250 of a second as against 1175 on one of the other cameras. As for the lenses, you should be able to make good petters with any one of them. All other things being equal, the deeding factor will be an individual one; how do the cameras appeal to you from the point of view of convenience and pleasure in handless.

Q. My . . . camera stops and speeds do not correspond with those on mv . . . exposure metter. Can you advise me how to use this meter scale with my camera ?—C. G.

A. It is generally more advisable in photography to give the longer exposure rather than the shorter one. We would suggest, therefore, that since the meter does not indicate a

speed of 1/75 of a second, you either use your 1/50 speed and ignore the 1/75 or adjust your daphragm indicator between stops, should you want to use the latter speed Similarly for the 1/200 speed, which does not appear on the meter scale A for the stop, the scale stop f/2 Bc can be used for both f/2 3 and f/3 on voir current: the scale stop f/4 for f/35 and f/35, and the scale stop f/4 for f/35 and f/35, and the scale stop f/46 for f/35 and f/35, and the lowing stops on your camera f/9, f/325 and f/36. The scale stop f/36 for f/36 and f/37 and f/37 and f/37 and f/37 and f/38 and f/3

Q. In order to obtain dark sky effects I wish to buy either an orange or a red filter. Will you please advise me which is the better one to buy?—L. K. M.

A Sometime ago the red filter was usually recommended to this purpose, but more recently the orange filter has taken its place in the peoplar favor One of the reasons is that the orange filter has a lower exposure factor than the red; in fact, it is usually about half, the red requiring about eight time of the orange conjugate of the red filter or the commend exposure, the orange only four. Another c ason is that the red filter debox a readency to thimmate detail in the

Q. When I wish to cut off part of a 35mm roll in my camera in order to develop a strip of film before the entire roll has been finished, how many frames must I lose in reloading the unused portion?—D. A.

A We estimate that in reloading the unused portion of the roll of film after cutting, you will necessarily lose about three or four frames.

It does sometimes happen that a few printare desired in a hirry. Many photographers, however, bus bulk film and load their own riels with lengths of film which will be economical and convenient for the subjects to be shot.

Q. Can you explain the meaning of the term "genre" when used in describing a type of picture?—A. F.

A This term refers to a picture that tells a story For example, two children at play, a laborer at work, the portrait of a woman kiniting or engaged in some kitchen chore, are typical gentre pictures. In short, any picture that shows a person engaged in doing something is properly classified as of the senie type.

Q. I am enclosing some prints and films; the prints have dark spots caused by corresponding light spots in the films. I have my developing done by a local concern and these spots seem to occur at random on different rolls. Some have suggested the spots were caused by error in developing and some by dirt or dust on the lens.—B. V. C.

A. An examination of the negatives shows that the high spots to which you refer are undoubtedly caused by incomplete development at those points. This may have been due to negatives streking together at the particular point and preventing full development or development blocked locally by some other unterference. The fact that the image is almost fully revoited at these points where the properties of the prevention of the button of the prevention of the precular point in question prevented a density comparable with the rest of the negative.

Figure 1. Bernhard Schmidt's first Schmidt camera photo, now historic

puting He also takes active interest in instrument design. The following is the article by Hendrix and Christie.

O'E of the most outstanding inventions in optics of modern times is to be credited to Bernhard Schmidt, late optician of the Hamburg Observatory in Bergedorf. The first Schmidt camera saw the light of day one sultry afternoon in the late summer of 1930 Using the camera as a telescope, Schmidt and a friend amused themselves that afternoon by reading the epitaphs on the tombstones of a nearby cemetery, and by looking at various buildings in the distance Among other objects was a windmill about two kilometers away, in Figure 1 the reader will see the reproduction of a photograph of this windmill, made by Schmidt with the first Schmidt camera This photograph was made on a moonless night with an exposure of two hours. On the original print one can actually count the twigs on some of the distant trees

As in most great inventions, Schmidt's method of climinating come and aberrations from reflecting telescopes is simplicity itself and, as one looks back, it seems incredible that no one appears to have thought of this simple solution long ago

Several articles have been written about the schmidt camera since the inventor set forth its principles in 1931, but luttle that is now has been included in these discussions. Since there are many ramifications of the Schmidt principle in this seemed worth while to discuss this remarkable camera and its applications fairly completely, for it will be found that there are but few fields in optics of the second of the sec

The outstanding defects in the images formed by lenses and mirrors are spherical aberration, comma, astignatism, curvature of the field, distortion, and for lenses we have, in addition, chromatism. Of these defects, only one is distributed uniformly over the schoole field, this defect is spherical aberration, all other defects are proportional to their distribute of the school field.

Now a spherical nurror has no axis and, furthermore, a mirror is perfectly achromatic, o, could we but find a method of eliminating spherical aberration from the images produced by a spherical conease mirror such a system should prove ideal.

Spherical aberration is caused by rays from various zones failing to come to the same focus, the more distant the zone is from the central ray the closer as focal plane is to the mirror. This defect, for spherical concave mirrors is shown diagram matically in Figure 2, at A Suppose now. we place a very small aperture in a screen at the center of curvature of a spherical concave mirror, as shown at B this aperture will limit the size of the incident beam so that the center and outer zones will come practically to the same focus for it can be shown that, for small apertures, and focal ratios less than f 10, the Rayleigh limit of $\lambda/4$ is not exceeded. If the incident beam by swung about the point o, all parts of the murror will be illuminated in turn and the focus will trace out the sphere al curve, ff, which has its center at o It will be seen that each point source of light toward which such an optical arrangement might be turned would form its image on the focal curve fl On increasing the size of the aperture the focus is no longer sharp spherical aberration is now appreciable, but we can eliminate this defect by introducing equal and opposite aberrations into the incident beam as shown in C These opposite correcting spherical aberrations may be produced by a suitably shaped lens, or mirror, placed anywhere in the parallel beam for one particular point

position common to all rays, that is, with the optical center at the center of cursature of the mirror. For many purposes a large field is not required and it becomes more convenient to move the correcting plate away from this position and perhaps moreproster at with some other optical surface, such, for example, as the face of a prison or the collimator of a spectrograph. The corrections, of course, are not identical for all positions of the correcting plate.

On introducing the correcting plate into

source of light, but when we are dealing

with more than one source it becomes im

perative to place the correcting plate in a

 possible—and practical—to distribute the required corrections between several surfaces when it is desirable to avoid deep or steep curvatures.

The curvature of the field may be removed (approximately) by means of a simple plano-convex lens placed immediately in front of, or in contact with, the photographic plate, the planes side facing the emulsion. The radius of this lens is f.3 for glass with an index of refraction of 1.50. This is satisfactory for cameras having an f ratio of f.3.

Applications of the Schmidt Principle: In the accompanying diagrams, Figure adaptation, which may be made used to be should principle. Undertunately, Schmidt fit no account of the various ramifications of his camera of which he must have though, and we do not know, in most cases, who originated the various arrangements we present, must of them have been divised beer, but we do not claim priority. In a few cases, where the originator is, known, we have appended his name to the diagram, although it is probable that offers interested in fast cameras may have indipendently thought of them.

In the central column of the diagrams we have arranged illustrations of the fundamental types of Schmidt cameras and, to the right and left, some adaptations of these

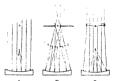

Figure 2. Spherical aberrations and Schmidt's remedy for them

types, most of which need no explanation. No VI, which shows the diaphragm replaced by a correcting mirror, is shown, as are most of these diagrams, in an exaggerated form: in practice it is necessary to reduce the angle between the incident and reflected beams to a minimum in order to reduce the foreshortening effect. A perfect correcting mirror should be figured in an elliptical form but, since such a figure is very difficult to produce, we must be satisfied with an approximation in the form of a circular correcting mirror. If the aperture ratio of a camera using a correcting mirror is small, a cancra using a correcting mirror is binary, the foreshortening will be negligible, and here we have a perfectly achromatic ar-rangement which should be exceedingly useful in working at the extreme limits of the spectrum.

When a Schmidt camera is constructed with an aperture greater than its focal length, the curves in the currecting plate become steep enough to introduce appreciable chromatic aberration. It however, the continuation of the con

food length, however, has been changed but little, and thus we can obtain the speed of an //0.66 camera with a field and correction-plate curvature of an //1.0 camera. This is shown clearly in Figure 4, where an ordinary Schmidt camera is compared with one of the thick mirror type

In such a camera the correcting plate is placed at a distance of R/2n from the front surface of she mirror, where R is the radius of the mirror and n the nides of refraction of the glass. This position is the apparent center of convature of the mirror as seen from the mirror surface. (In all cases where the focal curve hee at the surface of the glass the photographic emulsion should have a finn of all between it and the glass, in order to make optical contact. Cost-oil will be a finn of all between it and the glass, in order to make optical contact. Cost-oil will be a XIII. Figure 3, we have the extreme

SCIENTIFIC AMERICAN
24 West 40th Street, New York, N. Y.

form of solid type-one in which there is no medium other than glass between the correcting surface and the focus. This was first suggested to us by the late Sinclair We do not know of such a camera having been made and there are some practical optical difficulties to be surmounted in constructing a solid Schmidt, furthermore, the increased absorption of the thick glass becomes important, and, since it must be sufficiently homogeneous for its purpose, such large blocks are very expensive. The two parts, separated by the dotted line in the duagram, should be figured separately but when cemented together they must be accurately co-axial The photographic plate could be introduced into the focal curve through a hole in the half containing the

Ordinary Schmidt Comero

along the axis as shown

re "This Ho or" tone of fee

Figure 4: Ordinary and thick mirror Schmidt cameras compared to scale. Index of refraction assumed to be 2 correcting surface, either from the side or

The difficulties of the extreme thick mirtrypes may be extreme the avaration of Wright's "Anniteur Tele-cope, Making-Advanced") system, that is, by placing the correcting surface at the focus as shown in XY; but here we are confirmed with two non-spherical surfaces, extrinely difficult to figure in conjunction with each other An experimental ramera of this type, with an aperture ratio of J', was constructed here, but it was not a success because the higher order abertations randered the images unsatisfactory. It is possible that a camera, geometrically J4, or with an equivalent focal ratio of J'3, would be entirely satisfactory.

One of the neatest of all solid type, as that shown in XVII—the folded solid Schmidt, designed by Hendrix Here we have fow practical optical difficulties, all though there are four components of the seven plans surfaces only the hyporenise of the large prism must be worked to a high degree of precision, the cemental surfaces are sufficiently accurate if worked to a waye because the cement, which should have an index of refraction equal to that of the glass, fills in the irregularative between the surfaces. Small errors in the thickness of the components may be retrified when adjusting the small prism during the final sessembly.

The "off-axis" type, illustrated in XX, is exceedingly useful in practice because, with this arrangement, the photographic plate or film may be placed outside the light beam This system also is adaptable for visual observations. Making a single off-axis correcting plate of large dimensions is, unfortunately, somewhat wasteful of time and material, because it is necessary to figure a correcting plate of more than twice the required diameter. If more than one camers of the same focal length is required, the waste is reduced, because several off-axis plates can be cut from the original one. This type seems to be the only practical one for mass production.

mass production.

In XIX the Schmidt principle is used in the form of a microscope. Such an arrangement might prove useful for low-power work, where a large field is desired, used as in microphometery, but perhaps the most ingenious arrangement is that of Hayward, XXI, in which he suggests a thick micror with the foral curve ground out of the mirror fax, and serving as a reservoir portion of the spherical mirror serves to admit labil for dark feld illumination.

The Design and Construction of Correcting Plates: The deviation, Δ, of the surface of a correcting plate from a plane is given by the biquadratic parabola

$$\Delta = \frac{x^4 - kr'x'}{4(n-I)R^3}$$
(1)

where x is the radius of the zone, k, a constant, r, the radius of the correcting plate, R, the radius of curvature of the spherical mirror; and n, the index of refraction of the glass

Now, let
$$t(n-1)R^3 = \frac{1}{K}$$
 then (1) becomes $\Delta = x^*(x'-hx')K$ (2)

which is in a convenient form for computation (giving k various values from -10 to +3.0, we obtain the series of curves shown in Figure 5. When k=0 we have a lens with a sharply turned up edge and flat in the center. This form is one of the most

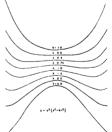

Figure 5: Correcting plate curves

difficult to figure, yet the writers have seen it recommended for anatural As k is increased the center rates and the edge is a
depressed unit, when k is unity, edge and
depressed unit, when k is unity, edge and
center are equally high, and the depressed
from the lens surface is a minimum and
it is this figure which we have found most
it is this figure which we have found most
astisfactory for general purposes; it is also
the easiest to construct. When k=1.5 we
have a correcting plate in which the effect
of chromatic aberration is at a minimum.
This is the type of correcting plate which
we have used for our "thick-mirror Schudid".

structed here. When k=2 the neutral zone is at the edge of the plate and the figure becomes difficult to achieve in practice. In all plates the edge gives some trouble while figuring, because of the flexible nature of the tools used in this work, hence it is best to make the plates at least 1" larger than the required diameter; the troublesome edge can then be masked out when the camera is assembled It is estimated that the cost of labor in making a correcting plate is reduced at least 50 percent by making a generous allowance for the edge

Differentiating (2) and equating to zero, we have

$$x^{t} = \frac{kr^{t}}{2}$$

This gives the distance of the neutral zone from the center, and, by substituting this value for x, in (2), we obtain

$$\Delta = \frac{k'r'}{4}K$$

the depth of the curve at this zone. With these two dimensions, (3) and (4), at our disposal the correcting plate may be rapidly roughed out to shape, the depth of the zone being measured with a suitable micrometer

The angular field, \$\theta\$, of a School camera is given by the equation

$$\frac{\theta}{2} = \frac{d'}{2j}$$

where d' is the diameter of the plate holder and f is the focal length of the mirror, and m order to utilize all the light, the diameter, D. of the mirror must be

$$D=d+2d'$$
 (6)
where d is the diameter of the correcting

plate For ordinary purposes d' should not greatly exceed

3 The correcting plate is made from planeparallel glass plates free from strike It is very important that the plates be planeparallel, especially for telescopes used for stellar photography If the plates are not plane parallel, ghost images, caused by the internal reflections in the lens, will be formed to one side of the brighter stars. (It has been suggested to us that these ghost images might prove useful in stellar photometry.) When the plates are plane-parallel these spurious images fall on the image of the star causing them. For ordinary work a high-grade plate glass, such as Caystalex, may be used, but when high ultra-violet transmission is desired, glass such as Schott's U.BK5 or Vitaglass must be used A satisfactory thickness for the correcting plate is of the order of 1/40 to 1/50 of its diameter.

The plates are best supported, during grinding and polishing, on a circular felt pad which should be shrunk before use. the pad should be a little smaller than the lens. For small lenses the glass is held in position by a metal ring slightly larger in diameter than the disk and projecting above the level of the turntable by an amount sufficient to hold it in place, but not high enough to interfere with the motions of the tool. During grinding and pol ishing the plate should be rotated frequently upon the felt base. In the case of large lenses the plate is best retained on the table by means of sets of vertical spring bronze "fingers" attached to the turntable; at least six such sets should be used.

It will be floted that a certain polishing action is going on, on the rear surface of the plate, during the polishing stage, due to

WASHBURN PURIZONE CO., Inc., Providence, R. I. the motion of the plate upon its supporting pad which is difficult to keep free from rouge at this stage. The effect of this is eliminated, sterr the required figure has been approximated on the front surface, by making the final corrections on the back. During granding no abrasive should reach the back surface of the correcting plate because of the protective gap between the felt and the edge of the lens. Chris is the reason for cutting the felt disk smaller than the plate.

The best form of tool we have found for grinding out the zones is constructed as follows Three triants (120-degree sectors of circles) are cut from moderately stiff springbronze sheet in such a manner that the grain of the metal-that is, the direction in which the sheet was rolled-is the same in each. These sectors are then cut into radial "finto the underside of the extremities of which are cemented the grinding facets These facets are cut from unglazed ceramic tile, such as the small size used for bathroom floors. The sectors are then attached to a suitable hub and, if necessary, the fingers may be bent downward and outward, keeping the outer ends parallel to the surface of the plate.

Polishing is done with facets of moderatily soft putch attached to a sponge-rubber base about ½" thick, the rubber permitting the tool to conform to the zonal curvature of the correcting plate. Polishing tools with a sponge-rubber base will be found excellent for working on all optical surfaces where zonal curvature exists.

It will be realized, we think, that all but the smallest tools are of the ring form For smoothing out irregularities in the curvature of the zones a small common tool, one quarter, or less, of the diameter of the plate may be used. This should be given a long elliptical stroke in the direction of the zone

Schmidt's method of polushing correcting plates was to place them concentracilly on the lip of a shallow circular metal pan, the edge of which was ground so that an airtight seal could be made between the glass and the metal. The air was then pumped out of the pan, causing the orenter of the plate to be depressed; then, by the use of a spherical automatically polished to shape. This method is not to be recommended, however, except for mass production, when it becomes the modula operand in

The figure of the plate may be examined uring the grinding state by dupping it into a solution of ethyl communic and Xyloi maxed in a proportion of 4:1. This forms a smooth coating which has approximately the same index of refraction as the glass. After a little experience it is surprising how readily indirect wisual inspection of the form, using a good straightedge held in contact with the plate as a guide for the eye.

The Chinese mirror effect as sometime useful in correcting local irregularities, and even in polishing and figuring plates with small curvature. The lens is here supported on suitably shaped pads of semi-cured ruber, such as that used for patching automobile inner tubes; the part of the lens thus supported is abraded more rapidly than the unsupported regions.

A number of methods have been worked out here for testing correcting plates, some of which will now be described. The figure of the correcting plate may be readily esamined with a knife-edge if one has a telescope sufficiently large to take in the collimated beam from the assembled camera, as shown in Figure 6 at A. Using this method, a point source of light is placed at the focus of the camera, and the knife-edge at the focus of the telescope. The sensitivity of this focus of the telescope. The sensitivity of this of the focal length of the telescope to that of the focal length of the telescope to that

Where a large telescope is not available for testing we can make use of a small one, in conjunction with a pentagrism or an

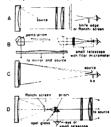

Figure 6: Methods of testing correcting plates for Schmidt types

optical square, as shown at B Here we have a small telescope rigidly set up at right angles to the axis of the camera. The optical square, consisting of two plane mirrors ounted at an angle of 45 degrees, or a pentaprism, is set up in front of the telescope on a base which may be moved across the collimated beam of light. The image of the light source is focused on the intersection of a pair of cross-wires in the focal plane of the telescope. As the pentaprism is moved across the collimated beam the image should remain on the vertical wire; any lateral motion is due to the poor figure of the optical system, vertical motions may be due to irregularities in the motion of the pentaprism.

An excellent test for cameras having an aperture J/S_0 cless, a made by placing the correcting plate directly in contact with the mirror, as at C_1 . The test is made on the axis of the lens, in a manner similar to that used for testing a parabolic mirror in the center of curvature; that is, by measuring the apparent radius of curvature of the various zones with a knife-edge at the focus. In this case the test is twice as sensitive as that for a parabolic mirror because the light passes which characteristic through the lens. The formals now becomes $\Delta R = \frac{C_1}{R_1}$; thus, when both knife-

edge and light source move together.

A Ronchi screen placed inside the focus of a Schmidt camera will form a series of fringes on a screen placed at a suitable distance from the focal point, as shown at D.

tance from the focal point, as shown at D. By using an opal or ground-glass screen these fringes may be examined readily. Each frings should be straight with parallel boundaries, but the presence of zones in the correcting plate distorts these fringes which are interpreted in the usual manner. The familiar Rouchi screen method of testing is excellent, also, for lenses with large aper-

ture ratios, or where the focus is too short for the eye to focus on the equivalent plane

An illuminated, small, silvered glass bead serves as an excellent point source of light for testing purposes The illuminating beam should be concentrated on the face of the head facing the mirror or lens to be tested. Any stray light which passes the bead should he blocked off by a suitable diaphragm placed behind it-a totally reflecting prism is excellent

To test a correcting plate made to work in the extreme regions of the spectrum (infrared or ultra-violet) we can construct a testing mirror of radius R' so that, in equation (1), $(n-1)R^* = (n'-1)R$

and thus make the tests in visual light which gives an index of refraction of n

There are, of course, numerous other methods of testing correcting plates, but those given here are sufficient, we think, for the average reader. It must be remembered that the plates, to begin with, must be plane-parallel, and they must be free from strike In selecting plate glass for correcting plates, shorts should be first tested with a micrometer for uniformity of thickness, and then tested for striae by holding the sheet between a small bright source of light, such as an arc, and a white screen Shadowlike streaks on the screen show the presence of these defects, and their positions can then be marked on the glass with a wax pencil I nless a large plate is required an area large enough for the purpose usually can be selected from relatively cheap glass-Pasadena, California, March, 1939

MII's completes the article by Hendrix latter states that Schmidt died about four years ago. His only article appeared in Central-Zeitung fur Optik und Mechanik. Bund 52, Heft 2, and in Mitteilungen Hamburg-Bergedorf, Bund 7, No 36, under the tatle of "Fin lichtstarkes komafries Spicerl. system

Because of his full occupation with important optical work now in progress at Pasadena, the sensor author soncerely regrets that he will not at present find it possible to answer requests for further information.

Ave , New York, N. Y.

The Schmidt camera gives great promise in astronomy, professional and amateur, and there is lots of work for the amateur to do with it. Heretofore a heavy discouragement in undertaking a Schmidt has been the interminable job of excavating the very deep curve of the primary—about 1/2" deep on a

121/2" disk. It is hoped that plans under way as we go to press will make possible the purchase of pre-roughed-out 121/2" disks. Last April this column stated that two off-axis mirrors had been made at the Mt. Wilson shops, we learn that two dozen is more nearly the correct number.

Stellafane convention, Sat., July 22

Convention of amateur astronomers, including planetarium show and banquet, at Hayden Planetarium, New York, Aug. 19 and 20. Former day will also be Amateur Astronomers' Day at World's Fair; Professor Shapley will give a talk. A three-week exhibit of amateurs' work will be held at Hayden Planetarium July 30 to Aug. 20.

ASTRONOMY

By William T Skilling, San Diego State College and Robert S Richardson, Mt. Wilson

M ORE ideally than any of the general treatises on elementary astronomy heretofore available this new work seems suited to the isolated reader. Its senior and thur has long tought astronoms in the classroom and knows the corners where the be ginner usually is perplyyed, mainly in the parts having to do with the positions and motions of the heavenly bodies. He set out to make these things as easily comprehensible in a text as they are in a classroom discussion, and the result is success. The explanations are in simple, homespun words and phrases, and are illustrated with home ly drawings that go to the heart of the chief difficulties. The whole of astronomy from systematically covered to the reasonable depth to which the average layman cares to go. Contrary to a widespread misimpression, this book, like all other elementary textbooks of astronomy, does not contain more than I percent of mathematics-the mathematical parts of the science being reserved for special advanced books (579 pages, 512 by 8½ inches, 248 illustrations) \$3.10 postpaid —4 G I

TRADE MARKS AND UNFAIR COMPETITION

By ORSON D. MUNN

A Trade Mark is an intangible asset of a business, yet
its actual value may grow so
large that it becomes the very
foundation on which depends
the whole structure of the
business. Because of this fact,
every business man should
have available such information on trade marks as will
enable him to judge with a
fair degree of accuracy the
desirability of any mark
which he may be considering.

Here, in one handy volume, written in non-legal terms, is a simple yet comprehensive interpretation of the Federal statutes and the body of common law relating to trade marks and unfair competition.

GLASS HOUSES

PEOPLE who live in glass houses not only should not throw stones but should make sure that they do not infringe a patent recently allowed by the Court of Customs and Patent Appeals.

The inventor of a glass brick applied for a patent on the brick and on a type of build ing construction using it. The patent was refused by the Patent Office and by the Board of Appeals However, the decision of the Patent Office and the Board of Appeals was reversed by the Court of Customs and Patent Appeals and the patent was allowed The brick in question was a hollow glass block having at least one side thereof fluted or ribbed so as to form prisms. The prisms were so formed that downwardly slanting rays of light such as sunlight, when passing through the brick were deflected in an unwardly slanting direction on the opposite side of the brick When bricks of this character were used in constructing a wall the sunlight passing through the wall was deflected onto the ceiling in the inside of the structure Prior to the development of th brick in question hollow glass bricks had been employed but these bricks were n provided with prisms to cause the deflection of the light upwardly in the manner described above

The Court pointed out that the indirect lighting effect caused by the prism arrangement on the new brick was not obtainable by the old type of brick. It was accordingly concluded this since the structure was now and since it produced a new result it constituted invention and that a patent should be granted. In support of its decision the

"It seems to us that the concept of causing deflection of light rays in the manner which has been described was inventive." To consummate the ronception and embody it in structural form must have required calculations based upon the physical laws re lating to light, and, finally, experiments to determine whether the result desired had been obtained."

AIR SPUN

FaCE powder and graphite were held not to be goods of the same descriptive properties in a recent decision of the Court of Customs and Patent Appeals involving the trade mark "Air Spun." A prominent manufacturer of graphite attempted to register then name "Air Spun" as a trade mark for graphite and the registration was opposed by a owner to manufacturer who used the same name as a trade mark for face powder. The reasons urged in support of

the opposition were of a rather unusual character. Thus the cosmetic manufacturer asserted that graphite was used in lead pencils, that the public generally associated lead with lead pencils, and that lead, which at one time was employed in face powders and face lotions, was regarded as a harmonial ingredient Because of three facts in was argued that some customers might be led to believe that "Ar Spun" face growder contained lead of the graphite manufacturer that the properties of the propert

The Court rejected this argument, however, and held that any damage that might result to the countrie manufacturer by the reason of the use of the trade mark. "Aur "Spin." by the graphite manufacturer was of such a remote and speculative character as not to justify refusal to register the trade mark. It was also pointed out that the goods were of an entirely different class, that they did not look alike, were used for different purposes, and were purchased by different classes of customers.

DISC LAIMER

O SE of the most unsatisfactory portions of the patent law is that portion dealing with disclaimer's little disclaimer's Shut disclaimer should be strenge, has claimed more than his mention, he must without unreasonable delay disclaim that which is not his invention in order to reap the benefits of the remainder of his patent.

There has been considerable confusion ato when a disclaimer should be filed and ato the subject matter which should be disclaimed Today it is generally accepted that when a court of last resort has declared some but not all of the claims of a patent to be invalid the patentee has a choice of either acquiescing to the decision of the court and filing a disclaimer or of rejecting the deci sion of the court and relitigating the quetion in a different court in a suit against a different infringer. Where the patentee elects to follow the second alternative he is risking the danger that the second court will agr with the decision of the first court and hold the same claims of the patent to be invalid. in which case the entire patent will be unen forceable because of the failure to file a disclaimer within a reasonable time after the first decision. Thus it will be seen that in every instance where a portion of a patent is declared to be invalid by a court of last resort a patentee is confronted with the nonetoo-pleasant choice of either emasculating his patent by disclaiming some of the claims thereof or of risking the validity of the entire patent by failing to file a disclaimer within a reasonable time after the first de-

thind. United States Supreme Const in a territory of the state of the

The Court held that the patentee had elected to disclaim the portion of the patent which had previously been declared invalid and having made that election he should have disclaimed all of the claims covering that subject matter. As a result, the suit for patent infringement was dismissed for the rather technical reason that in fling its disclaimer the patentee had failed to disclaim everything that he should have including. This decision represents one more reason to the patentee of the patentee had a patentee or rights for seemingly technical reasons.

RUBBER FAN

THE popular fans having rubber blades which waft summer breezes at us without benefit of a protecting guard were involved in a recent suit for patent infringe-

The owner of a parent covering a for of thes character browds unt-charging that a some-shat similar fain made by a competitor of the character beautiful produced as a competitor infringed his patent. The parent disclused a fain having rubber blades which were inserted in areaste groover provided in the blub which supported the blades. The areaste growers held the blades in corput position stand the axial throat required for rotation and at the same time were sufficiently reshert to yield when they came into contact with rigid objects. The rubber blade substantially climinated the danger of injuries reviting from connect with the rotating bladesulting from connect with the rotating bladesulting from connect with the rotating blade-

One of the defenser rused in the out was that the mere use of ruther in making fan blades did not constitute invention. The court rejected this contention, pounting out that the patient related to more than the meruse of ruther. It unaght the use of a flexi ble material in the making of fan blades and the supporting of the fan blades in such a manner as to give them sufficient rigidity to preserve their usefulness while at the same time preserving the inherent resiliency of the sister.

In this connection the Court made the following statement

"While the more use of rubber in making in hides was no invention, the use of a flexible material, which might of course be rubber, in the way the pateriate taught how to use it to obtain the desired results by at acting at in his way to the hub to increase its utility as a fan blade without destroying may appreciable way its inherent safety qualities, was what the patent law is designed to protect."

50 YEARS AGO IN .

(Condensed From Issues of September, 1889)

TELESCOPE MIRROR-"A means whereby concave mirrors of leng focus may be readily produced from plane-faced mirrors is illustrated herewith. To make such a mirror a pan is employed. preferably made of cast metal to be extremely rigid, and with flanged edges by which it may be bolted by three equidistant bolts to the flanged end of the tube. This pan is formed with a seat or shoulder, as shown in the sectional view, upon which there is placed a plane mirror, through the axis of which there is drilled

a small bole adapted to receive a tube, with threaded ends to engage an upper and a lower disk, fitting on the upper and lower faces of the mirror. The bottom of the pan has a central lower laces or the mirror. The bottom of the pan has a central aperture through which is passed a headed and threaded tube engaging the other tube, and the tube passing through the bottom is turned by means of a suitable wrench, to draw the center of the mirror down against its own rigidity, bending it into concave shape."

TUNNEL-"The Hudson River tunnel, designed to give passage for railway trains under the wide body of water that separates New York from Jersey City, is again in process of construction. Vertical shafts were sunk near the shores of the river The one on the west shore is sixty-five feet deep, circular in section, and thirty feet in internal diameter. The walls lining it are four feet in thickness. From these as starting points two tunnels commence, diverging slightly and coming later into parallelism with each other. Each tunnel is lined with a shell of steel, built up of plates secured at the joints by angle irons projecting inward. The steel is three-sixteenths thick as at present used. Within this shell a brick lining is placed, of the best brick, laid in hydraulic cement mortar. The brick lining is two and one-half feet thick."

MORTAR---"A new idea in Germany is the wholesale manufacture of mortar of the best quality, to be sold to small builders and private individuals. Some 2,000,000 bbl. were thus sold last year in Berlin. This obviates the necessity of making the mortar on the ground under unfavorable circumstances and at unnecessary expense.

TUBING-"Considerable interest was shown at the Brussels exposition in a flexible metallic tubing exhibited . . . formed by wrapping strips of metal spirally around a mandrel. The metal strips were bent over at both sides and a thin, narrow rubber band was

inserted to prevent leakage. The tubes could be bent in any direction, were perfectly tight, and were claimed to possess great resist ance to both internal and external pressures, and to be easily bandled and repaired"

ALUMINUM-"The Pittsburgh Commercial Gazette says: Few persons are aware that an aluminum-making plant is now in full operation in this city . . About fifty pounds of aluminum metal are produced daily it is worth about \$4 per pound, and this is a very large single output when compared with the product of the factories in other parts of the world. The material is used for various purposes. It has taken the place of silver leaf in sign paint ing, and in that particular has proved a great success.

TALKIES-"At a recent meeting of the French Academy M. Lipp man presented a note by M. G. Gueroult, in which it is suggested that by the combined use of a phonograph and an apparatus for instantaneous photography and reproduction of the pictures obtained, it would be possible to reproduce at any future time not only the speech of a person, but also bring before the audience a vivid picture of the person's gestures and facial expression

PAST GLORY "In 1880, the total tonnage of the English mer chant marine was 18,000,000 tons, and that of the United States 9,000,000-a tonnage four times as large as that of France. American ships monopolize nearly 20 percent of the total receipts of the commercial maritime carriage of the world. France and Germany figure in this commercial contest only for 5 percent each

LAMP "A new type of semi-incandescent lamp. . . consists of two horizontal rods of copper, set in line with each other, but separated by a space of about 3/16 of an inch A thin fluted carbon rod is set vertically, and rests upon the ends of the copper rod, forming a bridge across. The current passes through the copper rods and through the point of the carbon rod, which is thereby rendered brilliantly incandescent'

GUN-"The great 12 06 inch De Bange gun excites much attention at the Paris exhibition. It was tested on the trial ground at Calais on May 7, 8, and 9 last ... The greatest range was a triffe short of twelve miles A war ship capable of carrying and discharging these weapons might he three miles out in the ocean off shore at Coney Island, and throw projectiles into the cities of New York and Brooklyn. Our war department should begin to think about obtaining some of these arms."

ELECTRICITY- "According to reliable reports, there are at present 3351 isolated electric lighting plants and central sta the United States alone, operating 192,500 arc and 1,925,000 in-candescent lights each night."

OUR POINT OF VIEW

Oily Outlook

PETROLEUM, black gold of the oil more ways than one has made possible our highly developed automotive age, holds forth promises of even greater marvels in years to rome. Given a quantity of petroleum, the modern resemblements produces an awer-inspiring variety of materials which, in one way or another, can militunee, even change the mode of, our daily lives And this he does with what, in the future, will be considered to be a meager knowledge of his subject.

Meager though present-day knowledge may be, developments in the field of petroleum research make it possible for the technologist with a flair for prophesy to give us a well-founded glimpse of what the future holds in store. Thus, Dr. A. E. Dunstan, British petroleum technologist, did not stretch facts beyond possibilities when he visualized the petroleum home of the future where even the food served will, in part at least, be derived from petroleum. Briefly described, Dr. Dunstan's dream home will have a roof of petroleum-base tile and walls of synthetic glass or hollow brick, while doors, partitions, windows, and even furniture will be fashioned of some form or another of petroleum-extracted plastics. Decorative effects will be obtained with similar plastics, aided by brilliant or subtle colorings skilfully obtained from through the use of petroleum dyes.

The people who live in these petroleum-created homes will even wear clothes whose origin will lei in petroleum. Fibers made from a petroleum base will be woven into fabrics that, in turn, will be colored with dyes from the same source.

Synthetic food from petroleum will constitute at least a part of man's diet. Dr. Dunstan believes, and backs up this thought with a reference to the fatty acids that can now be extracted from petroleum. These substances could very petroleum derivatives to form foods that would equal in nutritive value the animal and vegetable fatts of toods.

Whence will come the vast supplies of petroleum necessary to carry forth this program? Alarmsta would have that our petroleum reserves will be exhausted shortly. But improved methods of reclaiming oil from Mother Earth, new fields being explored, more officient utilization of petroleum, are all pushing further and further into the

future the time when the point of exhaustion will be reached. In the meantime, it is pleasant and inspiring to let the mind wander through new fields to a region where today's home will be yesterday's potential crankcase filling.—4. P. P.

Hypergeometry and Hyperperplexity

COME months ago-as long ago as March, in fact this journal published an article entitled "Visualizing Hyperspace," in which was discussed a fourth dimension of space and a method of visualizing exactly what this kind of space would look like if there were such a thing. From time to time since then the editors have received inquiries from puzzled readers who appear to be confused about a variety of questions suggested by this article. Is not time the fourth dimension? How do the mathematicians know that there are more than the three common dimensions with which we are all daily familiar? How many more dimensions are there and, anyway, aren't a good many of the mathematicians just a bit "teched"?

First, regarding time as the fourth dimension: True, time does figure in the so-called "space-time continuum," but not as an extra dimension of space.

Next, how do they know there are extra dimensions of space? They don't! They play with them, however, just as if they did exist. All the mathematician does is to take the algebraic formulas of analytic geometry which he has applied to three-dimensional space and go on developing them in the same way for added dimensional. It is a game but the matter ends there—that is, so far as they know, for it is of course dogmatic to assert positively that there are no exits space dimensions. All we can assert is that, if there are, man has never run across any read ones.

The mathematican is a whimsacle fellow who throughly enjoys deliberately creating a make-believe and then proceeding to show what would be the case if it were true. He does this samply because it is such fun. His brain is active and can't help playing these little games. And, at that, there is no crime in extending his logical processes out muto the fog, provided they remain consistent throughout—flat is all science

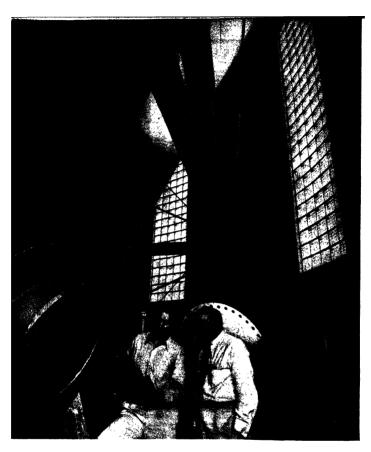

What probably confuses the puzzled non-mathematician is the fact that the mathematician uses for his excursions into the imaginary the same word he uses in connection with something he and all the rest of us knows to exist; that is, "dimensions" If he would call them something else the confusion would promptly end for most of us.—A. G. I.

Trees

TO say that all the lumber cut in the United States during the past 135 years would make a solid cube a mile on each dimension would not impress many people. We just don't visualize the enormity of such a cube. In terms of board-feet, however, the quantity shows up clearer and we begin to realize the inroads we have made on our timber resources A cubic mile of lumber would total considerably more than 1700 billion board-feet. Yet this is only a fraction of the drain on our forests, for the vastly increased demands for pulpwood-for paper, rayon, and related products-has denuded many thousands of once heavily forested acres And the continual process of cutting firewood and of clearing wooded areas for farming, as old farm soil wears out and is abandoned, is taking its toll.

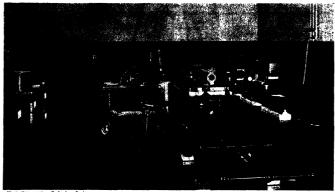

Conservationists are now, therefore, cheered by the news that farmers have more than doubled their tree-planting since 1935. The Forest Service of the Department of Agriculture reports distribution in 1938 of over 55 million tree seedlings and transplants as compared with a distribution of only a little over 26 million in 1935. The law providing for such distribution by the Federal Government in co-operation with state governments-the Clarke-McNary Law --- is not so new that it would provide explanation for this spurt in planting. It dates from 1924. The indication is that some other factor is involved, and we'd like to feel that it is a nascent consciousness of our sins of the past and of the great value of trees in our national economy-trees standing alone or in woods, forests, or wind-breaks,

The timber companies and the paper mills have that consciousness and are doing their share by reforesting as fast as they cut. New farm planting, if the idea continues to grow, will round out the cycle and assure maintenance of a continuing supply of wood for all purposes. New growth will be slow in maturing, of course, but we certainly must have reached the point where patience should rule—after our years of impatience to grab, before omeone else did, the golden profits from Nature's bounty of trees.—F. D. M.

WITHIN THE HOUSING OF A GIANT ATOM SMASHER

To "smash" atoms they must be bombarded with high-speed particles. One way to give particles high speed is with the cyclotron, while another is by means of an electrostatic machine. Better results are had if this machine is aperated in an atmosphere of compressed gas, and this has led to the installation of atom anashing equipment inside very large steel tanks to permit control of this factor. The photograph shows the exterior of the huge container of the Van de Graff generator now under construction at the Carraeje institution of Washington, inside its Insulex glass block housing.

A spectrograph of the kind used in measuring small amounts of impurities in metals, as in manufacturers' laboratories

Eyes That See Through Atoms.

(In Two Parts-Part One)

THERE exist a few scientific instruments which, though they have contributed directly to the establishment of no vast new factories, and are never sold over the counter, are of incalculable value to mankind. One of the most powerful and useful of these instruments is the spectroscope; indeed, Henry Norris Russell has called the spectroscope the Master Key of Science. It appears to be true that with this talented instrument scientists have succeeded in unlocking more secrets of nature than with any other single device. Though comparatively simple in its structure and operation, the spectroscope gives answers to an incredibly wide variety of questions merely by dissecting a beam of light and separating

this into its component colors. In life possible on Mars? Ask the spectroscope. Is a certain painter's illness caused by lead poisoning? The spectroscope can tell. How much does the core of a helium atom weigh, and how much that distant star? Does this greenhouse contain the correct amount of carbon dioxide to support plant life? Of what is the tail of a comet made?

"Obsyright 1839, by the Author, From the book "Atoms in Action: The World of Creelive Physics," by George Russell Harrison. (Shortly to be published by William Morrow and Co.) The Spectroscope, Long a Master Key in Science, is Proving to be of Major Practical Importance in a Wide Variety of Arts and Industries

By GEORGE RUSSELL HARRISON, Ph.D.

Professor of Experimental Physics and Director of the Research
Laboratory of Physics at the Massachusetts Institute of Technology

aton? Is this the sweater of the burglar who crawled through that broken window? How hot is the Sun? Thousands of such questions are being asked from time to time, and are being answered correctly with the aid of the spectroscope.

ANY atom or molecule will emit light if it be struck a hard atomic blow, and all light originates from atoms which have thus been simulated by heat or electricity. Since any material object—a star, a drop of blood, a speck of putty—is composed of atoms, any material object can be induced to emit light by heating at until it becomes an incandescent vapor. The light which is thus emitted carries inevitably in itself many secrets concerning the atoms from which it originated. It is the function of the spectroscope to analyze this light, and thus lay bare these secrets for the eye of science to read.

The chemist finds that a tiny pinch of salt needs more than a bathtub full of water in which to hide from the ferreting eye of the spectroscope, and he uses this instrument regularly to detect and measure minute traces of impurities in the materials with which he works. So bright is the light which the atoms in a small speck of metal can emit, that a piece of brass the size of a pinhead will serve for a complete determination of the presence or absence of 70 of the chemical elements, and none will be overlooked which is present in an amount as great as one millionth part of the whole. In fact, at least ten of the chemical elements were originally discovered with the spectroscope.

Atoms which are to be studied with a spectroscope need not be anywhere near it, for the light which they emit can travel a billion miles across space and still deliver up its secrets when captured

and analyzed. The astronomer is thus enabled to analyze the materials of distant stars, and has learned that even the farthest visible nebula is composed of the same atoms that we know on earthdust similar to dust across the vast stretches of the cosmos. More than three fourths of the discoveries of modern astronomy have been made with the spectroscope, and no large telescope is considered complete without one to sort out the light it gathers. Nor is the spectroscope merely an analytical tool, for with it stars and nebulae can be weighed, their temperatures taken, their speeds through space measured, and the courses charted of their lives and

To the biologist and physician also the spectroscope is invaluable, for with it such complicated molecules as those of vitamins and hormones can be studied, and metallic poisons can be detected in the blood long before they accumulate in amounts sufficient to be harmful. If the human body is analyzed down to its constituent elements, almost every kind of atom is found, but many are present in extremely small amounts. Which are essential to life and which are merely incidental? For example, little copper is found: too much copper is poisonous; yet some copper must be present if life is to continue. How much copper is too much, the spectroscope is helping the physician to determine. The same question must be answered for numerous other kinds of atoms.

Drugs also can be studied with the spectroscope. In cases where cocame posoning is suspected, a few drops of fluid taken from the spine of the patient can be diluted and the cocaine content can immediately be determined from its light absorption. To draw enough fluid to analyze chemically might harm the patient.

ENGINEERS find the spectroscope to useful also. With it they can look made the cylinder of an engine while this is in operation, and study the burning and explosion of gases and the propagation of pressure in the cylinder. A plug of metal is cut from the top of the engine and a thick window of clear fused quartz is inserted in its place. Through this window comes enough light to enable the spectroscope to establish the temperature of the flame at any mistant, and to give analyses of the composition and rate of burning of the fuel.

Even in crime detection the spectroscope is useful, and it has had its day in court in a number of lawsuite. In one case, gasoline which exploded in a sewer was traced to one of a dozen filling stations in the neighborhood from which it might have leaked, by using the spectroscope to show that the gasoline found remaining in the sewer

A newly devised automatic machine for measuring the wavelength of the light producing spectrum lines, directly from the positions of the lines on a spectogram. The spectrogram is clamped on the carriage in rear, the projection affectoroope above it throwing the spectrum on a screen in the center of which is a lit which admits the light to an electron multiplier. The carriage is moved by the lead-acress shown, and the dial geared to this reads in anastroms.

absorbed light identically with the brand sold by the station. The G-men their government laboratories use the spectroscope regularly, as do workers in the various state criminological laboratories.

The spectroscope is thus at once a powerful tool for analyzing matter: a super-telescope, and a super-microscope; a super-predometer, thermomored, and the super-masure and clock. In each role it exceeds in range and power the more common forms of these devices. This it can do because it attacks fundamentals; it studies the world and the heavens in terms of the very atoms of which they are made, and these atoms in terms of the energy which is their very life.

The foundations of spectroscopy were laid by a 24-year-old boy. One day in 1666 a young student, later to win fame as Sir Isaac Newton, threw the first purposefully produced indoor "rain bow" on the wall of his bedroom. Newton thrust a prism into a beam of light which was shining through a round hole in his landlady's windowshade, and saw that the prism split the white light up into a bright spectrum of colors. By so doing he came breathtakingly close to inventing a spectroscope. If the sunlight had entered through a crack in the shade instead of through a hole, and if Newton had turned his prism so that its base was parallel to this crack, and had inserted a pair of lenses into the beam, he might have noticed dark streaks or lines running across some of the colors on the wall. More than a century clapsed, however, before Joseph von Fraunhofer designed a spectroscope which would separate light into its ultimate purity of color, and observed these dark lines in the spectrum.

Despite its tremendous analytical powers, a spectroscope is really a simple instrument, and it has no moving parts to wear out. Light to be analyzed is sent into it through a narrow slit, and then passes through a prism or similar device which separates the different waves of light in accordance with their lengths. Waves of each particular length are sent in a particular direction, where they can be observed with a small telescope. The lenses in this telescope serve to heap similar waves neatly together in one pile, where they appear as a line of colored light, an image of the spectroscope slit in light of utmost purity.

THE great power of the spectroscope arises from the fact that under sufficient provocation all atoms and molecules emit light, and each of the kinds of atoms which make up our earth—iron and hydrogen and sodium and more than fourscore others—emits light of certain wavelengths and those only. Since light waves are identical with ultra-short radio waves, under proper stimulation every atom becomes in fact a tmy short-wave radio transmitting station. When a radio set is tuned to a certain wavelength a peak of sound intensity is heard if some station is

spectrum line is the peak of light seen at a certain wavelength because an atom is broadcasting on that wavelength. The millions of atoms in a fame or electric arc broadcast on hundreds of requencies at the same time, but the spectroscope can be tuned to all these wavelengths simultaneously, sorting them out so that all can be observed together without mutual interference.

Though the waves which the atoms emit bring no purposeful message, they tell much, and by literally reading 1,000,000 separate spectrum lines have been distinguished all told, and most of others distinguished all told, and most of others have been identified as caused by the light which comes from one or another light which comes from one or another cules of which matter is composed. Since one or two carefully measured lines one or two carefully measured lines will serve to identify the atom which emitted them, it thus becomes almost the impossible for an atom to make its identity if its light can be sent through a spectroscope.

The patterning of lines in a spectrum

A large diffraction-grating spectrograph. Light which comes through a slit at the far aide of the circular track, just to the left of the center, is spread by a diffraction grating in the black box at the right around the circle as a spectrum. Photographic plates are placed in proper positions to record the lines

between the lines (to seven figures, in fact) the physicist has been able to deduce many facts about the atomic world from the broadcasts which originate there. Most important is the identification of sending atoms merely by noting the wavelengths on which broadcasting is being done. Just as an experienced 1adio listener knows that he 18 hearing station WZZZ when he turns the radio dial to 422 meters and hears any sort of noise, merely because WZZZ is the only station which broadcasts on that wavelength which his set will pick up, so a spectroscopist knows that he is looking at light from sodium atoms when he sees the familiar vellow light of the sodium flame, because sodium atoms broadcast on the vellow wavelength 0.5893 micro-meters. (This is usually written by the spectroscopist 5893 angstroms. Ten billion angstroms is one

The spectroscopist can be even surer of his station identification than the radio listener can, for each atom broadcasts not on one wavelength alone, but on a whole group of wavelengths. Iron atoms, for example, when made sufficiently hot are found to produce more than 20,000 spectrum lines. More than

is a language which the spectroscopist has gradually learned to read clearly. As the series of irregular black marks on this page conveys certain ideas to a reader, so the unevenly spaced lines in a spectrum convey to the scientist flashes of information—here is iron, here arsenic, here are lines of copper and lead. Some of the lines are brighter than others, so the light can even be made to tell how many atoms of each kind are broadcasting—here is a great deal of iron, here a little arsenic, here too much copper in this lead.

Since the spectroscope arranges the spectrum lines in order of wave-length it is not necessary that they be seen in color, and they can therefore be photographed and later identified from their positions on the resulting spectogram. This method of observing spectra is now commonly used, both because the records thus produced can be studied at leisure, and because many spectrum lines are found in the ultra-violet and infra-red regions where they cannot be seen but can be photographed with ease. When a camera is thus used in combination with a spectroscope the resulting instrument is called a spectrograph.

Most small spectrographs contain a

prism to split the light which passes them into its constituent wavelengths. but large instruments use a more nowerful device, a scientific light-sieve called a diffraction grating. This is usually a highly polished mirror on which as many as 200,000 sharp, parallel scratches have been accurately ruled with the point of a diamond. These narrow scratches, when evenly spaced 20 or 30 thousand to the inch and accurately placed to within a thousandth of the thickness of a hair, sort the light waves into spectrum lines without the use of auxiliary lenses. Prisms must be made of transparent material; glass serves for visible light, but quartz is needed for ultra-violet and rock salt or some similar material for infra-red light. A diffraction grating ruled on a mirror has the advantage that it can be used with waves of any length, within reason.

LARGE diffraction-grating spectro-A LARGE diffraction grains appears room to house it, and can throw light into a spectrum stretching a hundred feet around a huge circle. Such instruments are giants compared with the most common spectroscopes, small brass tubes on tripods familiar in elementary science laboratories. The positions of spectrum lines can be determined to within 1/25,000 of an inch, and when such precision is attained the length of the light waves is determined to one part in 3.000.000. Since the light waves are themselves only about 1/50,000 of an inch long, their lengths can thus be found to within a few trillionths of an inch—a billionth of the thickness of a

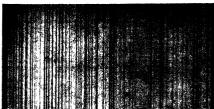

When a spectrograph is used to determine which kinds of atoms are present in a given sample of material, the sample is vaporized and a discharge of electric current is sent through it. The simplest method of accomplishing this is to strike an electric arc between two pieces of very pure graphite, and insert into this are the speck of metal or clot of blood which is to be analyzed, so that it is burned to nothingness. This burning tears the molecules of the material apart, separates them into their constituent atoms, and pounds each atom so hard with a deluge of electrons and other atoms that it emits the light which reveals its identity.

Suppose that a manufacturer of watches finds that a competitor is using a new hairspring of remarkable quality. This spring must be duplicated or improved on at any cost, but what can it contain that confers on its step the new temper and elasticity which are so desirable? If a chemist is to analyze the spring by ordinary means he must buy several dozen watches, extract their tiny springs, and then guess which substances are most likely to be involved, so as to select the proper

chemical reactions to carry out. He must dissolve and mix and scrape and weigh his materials with the greatest of care, for one single atom of a new alloying material to every 100,000 atoms of the watch-spring material may be responsible for conferring the high quality, and these are easily lost in a tiny sample.

How much more directly can the problem be attacked with a spectrograph! Now the chemist need merely strike an electric arc between two pieces of graphite, insert a small section of the extra-pure, 1000-proof gold which is the basis of the currencies of many countries is found to contain much atomic dirt under this revealing eye which sees through atoms, and if the average is like the samples which have thus far been measured, dross of various kinds totalling more than \$1,000,000 in supposed value exists in the gold of the world.

An entire freight train filled with pig-iron can be tested in a few hours by a spectroscopist dragging electric wires behind him as he proceeds from car to car, and carrying a small spectroscope

A typical section of a spectrogram taken by means of a large diffraction grating. This example shows the characteristic spectrum lines as emitted by iron

spring into the flame, and let the flash of light which results enter his instrument and be recorded. When the plate is developed it shows hundreds of spectrum lines, and from these can be selected those which are known to arise from each kind of atom. It is but the work of a few moments to identify lines of iron, copper, chromium, nickel-all common in springs of one sort or another. But here are some lines which belong to hafnium-there must be hafnium in the spring! That no metallurgist or chemist would have guessed that hafnium would improve a hairspring 18 of no consequence, for the hafnium is there, it is the only new element present, and the springs are strong and supple.

ALMOST any material can be burned in the blistering 9000 degrees, Fahnent, of an electric arc, and if a material can be burned its metallic constituents can be determined with the spectrograph, whether it be a sample blood from a patient suffering from lead polaoning, a drop of condensed mind of the polaoning of the polaoning

No metal has ever been made so pure that the spectroscope could not find impurities in it. Even the superfine, in his hund. Opening a car door he clips a wire to a sample pig, attakes an electric are between this and a bar of pure ron he carries, and observes the light in the spectroscope. If certain inpurity lines are brighter than a standard which his instrument shows, that pig contains too much impure metal, and he passes to another. By properly selecting samples at random the whole trainload of iron can be stead without bathering to unload if

Amounts of metal so small as to be difficult to detect chemically are often of great biological importance. Why, for example, do the livers of scallops concentrate cadmium?

A little copper is good for the diges-tion, but too much is not. In areas where many cranberries are grown, sprays have for years been used to kill pests, and the government at one time feared that the soil might have become so saturated with copper from these sprays that the cranberries might be absorbing more copper than would be good for the consumers. So cranberries, cranberry jelly, cranberry juice, dirt from cranberry bogs, and cranberry stems and leaves were all separately consumed in electric arcs and forced to reveal their copper content to the discerning spectrograph. Fortunately the instrument announced that all was well.

Very small amounts of lead or arsenic can do great damage to the human body, and lead poisoning is one of the greatest hazards of industry. Lead fumes are

found in some mines, and in storage battery and paint factories. Unless some care is taken to protect workers in these industries the amount of lead in their bodies may slowly rise past the danger point, and once this point is passed the resulting diseases are very difficult to cure. It is therefore important to keep a constant check on the lead content of the blood of such workers. By placing a few drops of blood from a worker in a tiny carbon cup and striking an electric arc to this cup, the blood can be vaporized almost instantly, and any lead atoms present will emit their characteristic light, which can be identified with a spectrograph This light being recorded on the photographic plate, a series of samples of blood containing no lead, but with varying known amounts of lead added to each sample, is burned and has its spectra recorded. The spectroscopist matches the intensities of the lead lines in the worker's blood with those in some of the samples whose lead content is known, and thus can measure amounts as little as one atom of lead to 1,000,000 molecules of blood. If a person be allowed to sleep for one night in a freshly painted room a definite, though harmless, increase in the lead content of his blood can often be observed with the spectrograph. Nor is this sensitivity confined only to lead, for any one of the nearly 70 other sensitive chemical elements can be determined as readily.

THAT two or three parts of aluminum to ready in a constant of the constant of

Chocolate and chewing gum manufacturers use spectroscopic analysis to maure that the lead content of their products is below the limit set by pure food laws. Have the arsenic and lead been properly removed from sprayed foods before canning? Is beer kept in cans dissolving anything more from the container than it would if kept in bottles? The spectroscope gives an easy, sure, and quick means of deciding.

So we find paper mainfacturers who want to discover the source of timy black specks in their spotless white product, producers of bakery equipment who wonder if their new coating compound for pans will contaminate the dough, spark-plug manufacturers who wish to study the effect of minute amounts of alkali metals in improving sparking, all finding the spectroscope helpful.

(To be concluded)

FIVE COMPANIES PRESENT: SAFETY

Superior Safety Glass... Four Times Safety Factor, Five Times Elasticity of Old Product... No Fogging... No Break-away... No Splinters

AMERICA'S 25,000,000 comfort-conscious motorists have grown safety-minded to auch a degree that they are quick to acclaim the development by science and industry of some noteworthy contribution that makes the automobile a safer mode of transportation.

Such a contribution is the new, lustrous, high-test safety plate glass which graces many of the sleek 1939 model automobiles, adding greater

safety and visibility. The glass has four times the safety factor and five times the elasticity of the old product It was developed during six years of intensive laboratory experiments by five large industrial firms at an aggregate expenditure of more than \$6,000,000.

Sharing in the development of the product, which has been made available at no increased cost, are E. I. du Pont de Nemours & Co., Inc., Libbey - Owens - Ford Glass Co., Monsanto Chemical Co., Pittsburgh Plate Glass Co., and the Carbide

sun. This enables the glass to retain its high visibility. Resilience of the glass is unaffected by extreme ranges of temperature, making it equally safe in summer and winter. It is easy to cut, facilitating replacements for damaged areas.

Statistics show that more than half of the injuries resulting from automobile accidents in the past have been

At right: Two research men stretch a piece of the glass "sandwich" filler to show its resilience. Above: Girl workers make the "sandwiches" by inserting a sheet of the polyvinyl acetal resin between sheets of polished plate glass

and Carbon Chemicals Corporation.
In perfecting the new glass, the laboratory technicians made a product that defies deterioration and discoloration, either from seepage of moisture and air into the "sandwich" plastic filler between the two sheets of plate glass, or from the actinic rays of the

attributed to flying glass. This danger is further less, ened by the new glass, because if it is broken by the impact of an object, the pieces adhere firmly to the plastic "sandwich" filler and do not fly about the car.

Because of its resiliency.

the new glass supplies ac cushioning effect when a body or head is thrown violently against it. There is greatly lessened danger of a fracture of head or limb as the glass gives readily and absorbs part of the shock. To test this feature, one of the research laboratories employed a professional stunt man to batter his beld head against

Repeated hammering on the new glass merely powders the surface

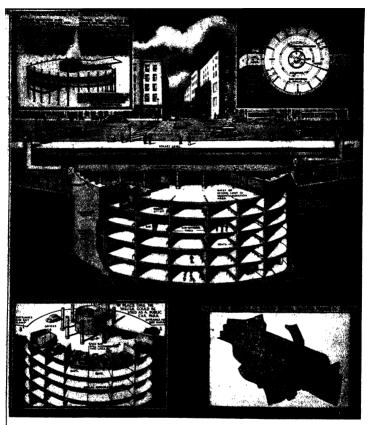

a plate of the safety glass. In repeated demonstrations, charging into the glass like a football player making a tackle, the man cracked the glass with his head but received no injury

DESPITE us greater resistance to breakage from sudden impact, the breakage from sudden impact, the combined and the property of the new glass enables a passenger, trapped an a car equapped with it, to push the glass out of its frame as a means of escape When the glass is broken up by hammering it can be rolled up like a rug without the particles of shattered glass pulling away from the plastic filler.

The plastic, or "sandwich" filler, is the principal factor in the success of the new glass. Although it is made under several trade names, the plastic has one chemical common denominator —polyvinyl acetal resin.

In the ten years that followed the first general use of laminated safety glass, alboratory technicians have bent every effort to produce the features which are dominant in the new high-test glass. Vinyl plastic is resistant to moisture, which makes it unnecessary to seal the edges. It will not separate from the glass under impact or when the glass is cracked or broken. Replacement areas are cut by scoring and cracking, drawing the glass says from the plastic, and cutture, it with a razor blade.

The new plastic may be produced either by calendering or extruding. The first method involves rolling and pressing out sheets of plastic, and the second forces the plastic at a doughty consistency through a narrow orifice. The resulting sheeting is quickly cooled.

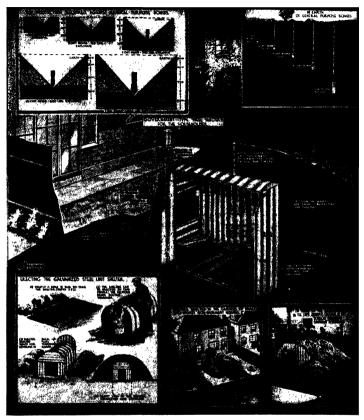

Bombing Raids Will Find London Prepared

NOT long ago a writer facetiously pointed out the irony of a certain "back to earth" movement that is taking place in large sections of the world. Primitive man (he reminded us) lived in caves or holes in the ground, but as he achieved civilization he came out into the air and sunshine. Down through the ages he progressed, built great clitics, mastered the secrets of the world about him. He rose to now and greater triumphs until he finally left the dirt and took to the air, glorously happy in his goddlick genius. And then the cycle suddenly begins again. One of man's latest and most spectacular achievements turned, like Frankenstein's monster,

upon its maker and sent him scuttling back to holes in the ground—modern, civilized troglodytes.

The analogy was interesting, the irony real, but the aforesaid writer intended only to provide a bit of humor to offset the seriousness of air hombing dangers. They are serious, indeed, as many millions of Englishmen will testify. London knows something of what may happen when and if enemy bombers fly over the city. Shanghai and Nanking, Madrid and Barcelona—current and recent brutalities—have provided the object lessons. But they are not enough, and London surmises many things more, takes no changes, provides against

many contingencies. Now London stands determined, methodically preparing against the day which the world hopes will not come. Intensively, the city and the surrounding country make their plans for lessening the danger and destruction of an air raid, having made up their collective mind to go back to earth, literally, should bombing planes arries.

A bombing raid over London would be no half-hearted sfair. There is no doubt that the enemies of Britain would stage a monater raid—or series of raids—in the hope of gaining a smashing victory. However this might affect the population, psychologically, and how great the destruction of property might be are besided the point at the moment; whether any great anmber of civilians might be killed would depend upon how well bomb-proof shelters are distributed throughout the areas involved. Plans have been made, considered, and discarded and other plans made up for large underground shelters that will house the multitudes during raids. On the opposite page is one suggested design of a structure which would be very effective, and it has the added merit of being useful during peacetime as a public car-parking space. Conceivably some of the large shelters may be built to this design or some modification of it. On this page are shown several views of one of the back yard shelters for residences. There are a number of variations of this type, protecting only against concussion and flying debris, being installed all over the threatened area. The inserts on the two pages show various details. This drawing is published through the courtesy of The Illustrated London News.

RIVER MODELS OUTWIT NATURE

NATURE poses no challenge more baffing to man than the one offered by flowing water. The enigma of flowing water is made the more challenging because it is presented before man's very eyes. Man can observe water in motion; he can photograph it and record certain of its physical dimensions; but he cannot explain what he sees and records. The road to geometry is indeed a royal boulevard compared to the byways which must be traversed by the hydraulic engineer.

The sad fact of man's mability to rationalize the phenomena of flowing water has not obviated the equally sad fact that often he must do something about those phenomena. Lands must

be made safe from flood. rivers must be made navigable, erosion must be checked, and so on. There are problems to be solved, whether or not the means for rational solution are at hand. Furthermore, the hydraulic engineer has not the advantage of being able to bury his mistakes. If the levee is built too low, the flood comes with redoubled fory; if the dike is built in the wrong place, the river steamer and its cargo end up on a sandbar. Having made it difficult to win. Nature nevertheless has not neglected to make it costly to lose.

When rational solution fails, man resorts to solution-by-trial. He calculates

things to the best of his ability, tempers, it is calculations with judgment, adds a liberal factor of safety-ignorance, build has structures, and hopes for the best. If calculations, judgment, and luck are good, the structures stand and serve their purpose; if luck or other factors are bad, there is a flood or an unnavigable channel or a dangerous crossion. Good or bad, the process of solution-usive in the way of self-safety and several the sive in the way of a disaster at worst, and expensive in the way of a disaster at worst, and expensive in the way of over-design at best.

Since the solution of hydraulic problems must, in the main, be by the method of trial (and error), it is idle to think of such problems in terms of absolute economy; rather, the hydraulic engineer thinks in terms of relative economy. And it must early have occurred to him to Miniatures of Rivers, Harbors, Dam Projects Solve Flood and Flow Problems... Considerable Design Ingenuity Involved in Model Making

By PAUL W. THOMPSON

First Lieutenant, C E, and Director, The U S Waterways Experiment Station

wonder whether the trial-and-error process might not be more economically accomplished if applied not directly to the waterway in question, but rather to a small-scale replica thereof. When that thought occurred to some early hydraulic engineer (could it have been during the conception of the Roman

A model of the river through Johnstown, Pennsylvania, by means of which a very serious flood problem was solved

aqueducts?) the now-flourishing science of analyses of hydraulic problems by means of small-scale models was born.

Today, few important projects involving the flow of water are undertaken without benefit of model-analyses. That statement is a paraphrase of the comments with which the English scientist. Sir Osborne Reynolds, concluded the account of his pioneer model study of conditions in the River Mersey in 1885. Sir Osborne's observations had convinced him that it would be "madness" not to take advantage of the small-scale model in designing any important project. The hydraulic world by no means flocked to get aboard the Reynolds bandwagon; but now, 50 years later, that world has practically accepted the Reynolds point of view. By the turn of the century, the German hydraulic engineers were model-minded; whereas, in America, the U. S. Waterways Experiment Station—now the largest of the world's hydraulic laboratories—has been in active operation for more than nine years.

What, then, is the small-scale modelthis tool which, while not eliminating

the necessity for solution of hydraulic problems by the method of trial, nevertheless enables the hydraulic engineer to do his trying and erring at relatively little expense? Briefly, the smallscale model, as utilized in hydraulic engineering, is a replica which acts like its prototype. The verb deserves the emphasis, for the essence of model-analysis is action. There is a technical expression covering the thought: dynamical similitude.

THE purusit of dynamical similitude permits of no side diversions. It demands compromises and apparent contradictions. Thus, in getting a model to act like its

ring a model to acr line in sprototype, it frequently is necessary to take steps which preclude the model coloning like that prototype. For example, a model of a railread truit look like the coloning like the coloning like the real thing. However, the details of its extens are quite different from those of its prototype. On the other hand, the model of the Ohio River at the Experiment Station looks like nothing in particular, but it acts like the Ohio River.

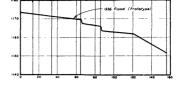

This distortion in the model's physical dimensions and appearance is a necessary evil, force on the experimenter by such hard facts as limitations of available materials; conflict of various forces; necessity for depths not less than certain minima; necessity for conomy; and other considerations. The model, in fact, represents a series of compromises,

an assembly of components in which one distortion compensates for another. The fact that the experimenter must distort, say, his model bed material (by using some material, such as crushed coal, which is available but is too heavy) makes it necessary for him to distort his velocities (by making them higher than they should be); and the fact that he distorts his velocities makes it necessary for him to distort his model roughness. The thought may be conveniently expressed by stating that the model-as-itshould-be is quite a different article from the model-as-11.19

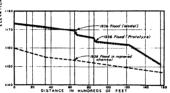

Consider again the model of the Ohio River, mentioned before Rational analysis does not even suffice to make that model act like the Ohio River. (In fact, were rational analysis equal to that task, probably it also would be equal to the task of solving the prototype problem and thereby the model study would be unnecessary) How, then, is it established that the model does act like the Ohio River? The simplest way to answer that pertinent question is to let it answer itself by means of an example.

One of America's critical flood problems has existed along the Conemaugh River and its tributaries at Johnstown. Penn-

sylvania. The great flood of March, 1936, was followed by a project aiming to increase very materially the capacity of the Johnstown channels. The project nowless despening the present channels, widening them, and, to some extent, realigning them. Details have been resolved by means of the small-scale model shown in an accompanying photograph. All horizontal dimensions on this model are 1/200 and all vertical dimensions are 1/80 of the corresponding prototype dimensions. Thus, the model-typer is

The three graphs referred to in the text, showing how the model reproduced the 1936 Johnstown flood and the height which the same flood would reach in an improved channel

relatively deep and steep. Meanwhile, the areas enclosed by tin walls represent city blocks. Certainly, the model doesn't look much like its prototype. How, then, is it established that the model acts like its prototype?

Consider the accompanying graphs. The solid-line curve in each graph represents a known event: the highest elevations reached by the water during the 1936 Johnstown flood. No conjecture or calculation enters that curve; it is compiled from gage heights actually observed and recorded. The dashed-line

curves also represent data actually observed--but on the model, not the prototype. In each case, there was being discharged through the model quantities of water corresponding accurately to the quantities which deluged Johnstown in 1936. The experimenter reasons that, were his model acting correctly, the dashed and solid lines should coincide He takes steps to obtain the desired coincidence, these steps consisting chiefly of roughening and smoothing operations. His progress may be followed through the middle and lower cents as satisfactory, and, secure in the belief that his model is acting correctly, he proceeds to the testing of the proposed plans. Incidentally, having successfully adjusted (or "verified") his model, the experimenter's worries are largely over Figuratively speaking, the testing of plans involves only the turning of a crank on a machine which it has taken months to build, calibrate, and adjust.

rate, and adjust.

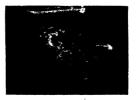

(As a matter of interest, not structly pertinent to the discussion of verification, there is plotted on the lower graph data indicating the effectiveness of the improvement plans. This curve represents the creat of a flood

resents the crest of a flood identical to the one of 1936 but occurring in a channel like the one proposed.)

IT will be observed that the smallscale mode in a very practical instrument. That is, it is designed and adjusted so as to aid in solwing a specific problem—such as the flood situation at Johnstown. It contributes only in relatively minor, degree to the advancement of abstract science. It is, in fact, only a semi-seventific instrument. That being the case, it is found not in institutions devoted to the development of fundadevoted to the development of funda-

Model analysis of a spillway problem. The object of the engineers was to reduce water velocities and eliminate dangerous erosion below the dam. At the left, velocity was hipl and scour so had as to cause much erosion. The model was then modified to produce lower velocity (right). Result was negligible erosion

mental truths, but rather in agencies charged with the prompt accomplishment of real projects. Thus, the Bureau of Reclamation maintains a modelanalysis laboratory at Denver, and the TVA maintains one at Norris The Corps of Engineers of the Army, charged as it is with the improvement and control of most American rivers and harbors, conducts model analyses in various laboratories, the largest of which is the II. S. Waterways Experiment Station. at Vicksburg, Mississippi. The photographs and figures accompanying this discussion relate to the latter laboratory. A further glance at its current operations will afford examples of most types of problems to which model-analyses are applicable.

Man constructs dams across rivers with various purposes in view to regulate the stream flow in the interests of navigation or flood control; to concentrate head in the interests of power development; to conserve water in the interests of irrigation Conduits and spillways frequently present perplexing problems, among which are the precautions to be taken to prevent dangerous erosion. The danger of erosion arises from the discharge at high velocities of water through conduits or over spillways. The problem is to reduce these velocities before the water reaches the soft materials of the river valley. In such case, the model-method of analysis

is easily and directly applicable. To describe by illustration, consider two of the photographs on page 141 that have to do with a model of the spillway for the Great Salt Plains Dam, about to be constructed on a tributary of the Arkanasa River. One of the photographis shows the high-velocity dascharge onto the erodible material; the other shows the results of provisions for the "stilling" of the high velocities. Relatively speaking, the erosion has been made readinable.

IN their natural states, few rivers are used in the susceptible of econome maygation Most of them must be "improved", that is, made deeper There are several methods of improving rivers for navigation day of improving rivers for navigation by cambration, as on the Ohio and the upper Mississippi; by increasing the critical or low-water flow, as on the Mississippi below St. Lunis Mississippi debow St. Lunis

Description of the open-river method of improvement movles consideration of of the elements of an alluvial river. Such of the elements of an alluvial river. Such is a stream consists of long, relatively deep pools, these extending along the concave sides of the river is as sides of the river is as sides of the river is as a riversing. The sides of the river is a series of flat, deep reservoirs, or pools, the water from one reservoir spilling into its downstream neighbor over the steep, shallow, crossing bar. Thus, the

situation facing the navagator is this: through perhaps 95 percent of his course he is m a channel having several times the depth his vessel requires; but, through the remaining 5 percent of the course he is crossing over bars where the depths very likely are less than he desires. The object of open-river regulation is to provide such training works as will cause the river to erode deeper channels over its crossing bars. In such a case the method of model-analyses hills an exercisely great need.

Man attacks his flood problems in various ways. by impounding the excess waters and releasing them only when they will do little or no damage, by increasing the capacity of the river channels: by constructing levees which exclude the water from restricted areas. The small-scale model is a valuable tool, both in enabling the engineer to select the method of protection best adapted to the situation at hand, and in aiding hum to develop details of design after the method has been selected. Two more of the photographs show the model reproduction of a bridge at Johnstown, one illustrating flood conditions at 12:30 A.M., March 18, 1936, while the other presents the improved channel taking all the flood water. Business in town goes on as usual

The unfavorable deal which Nature provides in connection with its pivers is repeated in connection with its pivers is repeated in connection with its harbors. The tides, the coera currents, the waves, and the hed materials blend together to form a phenomenon which man perceives clearly only in its resultant form. In the face of such complexity, the small-scale model is of only limited reliability, but so difficult are the problems that the aid and provided by a model, even of limited reliability. The requestly is valuable.

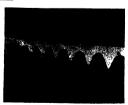

Thus, in the manner indicated by the examples cited, the profession of hydraulic engineering marches on, its progress over many of its most difficult obstacles being lighted by data from small-scale model experiments. One can say the same thing in another way; with which complexity with which was the baffling complexity with which conducted the conduction of the small-scale model.

Above: Waves impinging on a model of a breakwater. Such waves as these must not enter the harbor

In the Johnstown model: a bridge pust which flows the equivalent of the 1936 flood. At the left is the condition as it was and at right is shown the lower stage heights of the great flood with the improved channel

No More Blown Patterns

A SHOT-GUN shell recently announced, which will eliminate blown patterns, means much to trap and skeet shooters. Blown patterns—shotgun patterns with "holes" in them—have been a flaw in the art of mununtion making known to all manufacturers; and no amount of paintaking a munitor of the patterns out of every 100 flow of working the patterns out of every 100 flow of working the patterns out of every 100 flow of conventional shells, which unaccounts ably are much more widely scattered or "blown" than the others.

In the ordinary trap load, for example, 90 shells out of every 100 would put 60 to 80 percent of their pellets into a 30-inch circle at 40 yards. But the remaining 10 shells would all be helow 60 percent And three or four of these would seather their pellets so widely that barely more than 30 percent of the shot charge would get into a 30-inch circle at 40 yards. Even with the best of gun pointing, it is obvously sheer linck whether, with such a pattern, the clay target is struck by some of the

Top Wad in Shot-Gun Shell is the Villain That Causes Them . . . Elimination of Wad by a New Crimped Shell End . . . Unimpeded Shot Charge

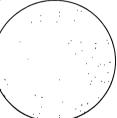

pellets or whether it flies blithely

Thousands of patterns have proved that the top wad is the villam in this story. With the top wad shead of it, the shot charge rishes from the muzzle at about 1200 feet per second. The terrific resistance of the air on the flat surface of the top wad at this velocity checks its speed and causes it to get in the way of the shot. Most of the time it slides along the outside of the shot charge or is flipned entirely out of the way and does little damage. But, about ten times out of every one hundred, the top wad obstructs the column of shot, and a blown pattern results.

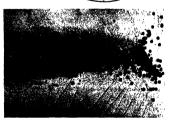

Shells with the new Remington Crimp avoid this effect, because they contain no top wad to get in the way of the shot column. They have exactly the same contents as are used in ordinary-crimp loads at present. To provide means of load identification and to waterproof the shell, a waxed paper disk only three one-thousandths of an inch thick is pasted to the crimp closure. On firing, the shot charge pushes the top open and breaks the disk into six pieces These remain affixed to the shell body. Hence, from the very beginning, the shot charge is completely unobstructed in its flight toward the target, and produces a blowproof pattern.

Above: Shot-gun shell at right is of conventional type in which the top wad causes occasional blown patterns. Other three shells show steps in folding and sealing the crimp of the new shell described. Lower right: The spark photograph shows how the top wad breaks up the shot charge. resulting in a blown pattern such as shown at the right. Lower left: Another spark picture reveals the continuous shot charge coming from the new type shell. Such a charge produced pattern at left

The illustration above, taken at a recent meet, shows
one of the competing planes an instant after leaving
the starting table. It has started from a standstill
under its own power. Below. A Syncro

Ace Special, less than five inches high

TINY gasoline engines with an average weight of only six ounces, a height of four inches, and a horsepower rating of one sixth are furnishing the motive power for proportionately small airplanes which have made remarkable endurance distance and altitude flights. The engines form the basis of a hobby which is daily attracting new recruits of all ages to the ranks of the gas-nowered model-plane enthusiasts. It has been estimated that there are more than a thousand clubs in the United States in which membership is exclusively confined to those model-plane flyers whose ships are gasoline powered. Doctors, lawyers, business men; all professions and crafts are represented in the ranks. They have taken the small plane from the classification of a boy's plaything and made it the foundation of a serious pursuit which helps to pay weekly wages in hundreds of retail hobby stores, in the factories where motors are manufactured, and in shops where plane equipment and materials are produced.

The hobby offers triple fun. First is the pleasure of building the planes and

Up in the Air for a Hobby

Half a Pound of Power . . . Avocation Makes Big Business . . . Inexpensive Midget Motors by Mass Production

By L. B. POPE

second the thrill of seeing them fly, the flights give a sense of adventure, and many an altitude record or transoceance hop has been made vicarously More important, though, is the very real toy of competition; flying the plane in one of the frequent inter-club or intraclub meets. Each "aviator" keeps formost in his mund the hope that his plane will someday establish an official record which will serve as a goal for the thousands of other model-plane enthusiasts throughout the country.

The reason for the recent increase in interest in gasoline powered model airplanes is not hard to find. The story is the familiar one of mass production making available a quantity of some product at a price within the means of all interested. The gasoline motors on the earliest model airplanes represented hours of careful planning and work. They were beyond the average model fan who had neither the equipment, skill, time, nor money necessary for their construction. But modern shop practice has changed the whole picture in favor of those who would fly gasolinepowered planes, but who for one reason or another cannot design and construct a suitable engine.

THE modern little power plants that records are carefully engineered working miniatures of those two-cycle gasoline engines commonly used for outboard motors, small water pumps, power lawn mowers, and so on. There are many manufacturers who offer a variety of designs and hence there is a wide price range from which to select. Partially assembled engine kits, requiring only a screw-driver for complete assembly, at about \$5 is the minimum. Complete motors with batteries, coil, tank, and accessories are priced up to \$22. The motors are rated at from 1/7 to 1/2 horsepower although they are only three or four inches high and weigh but a fraction of a pound when installed.

To arrive at a clearer idea of what a
model-plane motor really is, 16 typical

mode-piane motor reality is, 10 typical camples were selected and their characteristics averaged. The results give a hypothetical motor weighing six owners, slightly less than four inches high, with a hore-power rating of 1/6 at 8000 revolutions per minute. The both of the control of the co

Since this composite and average motor is only four inches high, the component parts are tiny indeed, vet standard machine shop practice is followed in the manufacture of all the various small parts. Most of the crankcases are die cast. Cylinders and pistons are usually machined from the solid, then hardened, ground, and lapped to fit. The pistons are smooth wall or with one or two piston rings Connecting rods may be die cast or steel drop forgings. with hardened and lapped bearing surfaces The crankshaft, drop forged or machined, has usually only one solid bearing area. (Some manufacturers advertise ball bearings at slight additional cost.) At one end of the crankshaft is the connecting rod and the counter-balanced crank; the propellor is on the hub at the other end. Between the two is the bearing, an inch or two long, of bronze or steel. A balanced flywheel, grooved for rope starting, is sometimes used on the 1/5- and 1/4horsepower motors.

A glance through the advertising literature of model engines will reveal such phrases as chrome-molybdenum crankshaft; tool-steel crankshaft; cad-mium-plated head; aluminum piston; micrometer needle valve; bronze bearings; transparent gas tank; or perhape

the maker will stress the fact that his particular model may be run either upparticular model may be run either upparticular model builder who has influence the model builder who has influence to model builder who has been position in this field, as in many other belds, work for the benefit of the consumer. In order to attract the public, each manufacturer constantly strives to improve his product.

The fuel system of these model-plane motors includes a gas tank, a needle valve, and an intake manifold. The tank may be of metal or some transparent material and is supported in back of or under the cylinder. It holds only a few ounces, as very little gas is required for the motors. The fuel is usually a mixture of gasoline and motor oil (S. A. E. No. 70) in the proportion of four parts to one. The fuel passes by suction through the needle valve and into the crankcase, where the oil lubricates the main bearing and other moving parts, and then into the combustion chamber where it is burned.

The electrical circuit of the motor includes batteries, coil, condenser, contact points, and a spark plug. Small flashlight dry cells are used to supply the necessary three volts. The coil and condenser together weigh only two or three ounces and furnish the hot spark which ignites the gas. The contact points are on the driveshaft directly behind the propeller and make contact once every revolution. Spark advance or retard, as may be necessary for proper operation of the motor, is accomplished by moving a lever located behind the hub. The lever shifts the ignition points forward or backward to make earlier or later contact. The spark plugs are made by several manufacturers, but are of standard sizes about one inch high and with 3/8-24 or 1/4-32 threads.

The planes which carry and are powered by these small engines usually are the results of hours of labor on the

At the right, an Ohlsson motor showing how the coil and con denser are connected Below. A Syncro motor with the gas tank as part of the streamlined crankcase assembly. Below, right: The baby Cyclone motor has a remote control

part of the owner. They may be bought complete or in construction kits, but frequently, they are the embodiment of the hobbyist's own ideas and the result of much personal experience.

With many different sizes and shapes of gasoline-powered model planes, some sort of regulations must exist in order to run competitions on a fair basis. Thus the National Acconaute Association, Model Division, has evablished contest classifications, and rules governing them, for all model planes including gas-powered types.

The models are classified according to the area of their supporting surfaces, most

supporting surfaces, most gas-powered models are in "E" class with an area of more than 300 squaltons are kept in mind while the plane is building, otherwise it will not be licensed and qualified for officially sanctioned meets. There are regulations governing minimum an amaximum weight, cross-sectional area of fuselages, and wheel size. The landing gear must be demonstrated to be strong enough to support the plane when gliding to a landing from a height of four feet, without damage and without nosing over

THE serious and adult nature of the hobby is shown by the official classification of contestants. No one under 16 years of age may compete without special permission and supervision. Records made by model planes are not

Photograph by Jacob Deschin
Details of plane construction. The large dry
cells shown on the ground serve merely as an
engine starting sid and are detached before flight

official until they have been accepted by the Contest Board of the National Aeronautic Association. Official recognition is given to duration records only. All official records must be made in all official records of the Contest Board of the N. A. A New records must exceed the old ones by 2 percent in order to qualify for recognition.

Official contest flights are made by allowing an engine run of 20 seconds. the time being limited by either a mechanical flight timer or by fuel measurements. In that time the plane must take off from a standstill and climb as far as possible. After the motor stops. the plane glides to the ground. The flight duration is timed from the instant the wheels leave the ground or starting table until they hit the ground. An indication of what these little planes can do is the winning time of a recent meet. First place was won by a flight lasting 20 minutes and 20 seconds. This means that the plane was so nicely trimmed that it soared in the air without any power for exactly twenty minutes Other non-competitive and non-official flights without the 20-second motor run limitation have been made which lasted more than two and a half hours. A welldesigned gas-powered model plane may cover 50 airline miles and soar to a height of more than 10,000 feet.

The surest way to antagonize any devotee of this universal hobby is to refer to his ship as a "toy plane," for they cannot truthfully be called toys in any sense of the word. The gas-powered model plane enthusiasts are a hard working and serious lost.

For those readers who want to obtain more specific information on this interesting hobby, and further details of planes, motors, and equipment, a list of manufacturers and dealers will be sent on request. Please enclose a stamped envelope.—The Editor.

A Remarkable Triple Star

VERYONE knows that hundreds by the spectroscope. As the stars move in their orbits, they sometimes approach us, and again recede, and the positions of their spectral lines shift accordingly. By following these changes. we can find the period of revolution in the orbit; but to work out its size is not so easy. If the orbit is turned edgewise toward us, the motion at certain points will be directed straight toward the Earth or away from it, and the spectroscopic observations will reveal the true speed. But if the orbit is tilted at some other angle, there will be no point on it at which the motion is in our direct line. Even at best, a large part of it will be sidewise, and only a fraction (in technical phrase, a component) of the velocity will be in the right direction to shift the spectral lines. In the extreme case when the orbit-plane was squarely at right angles to our line of view, there would be no change in the distance, and no Doppler effect, however rapid the actual motion.

It follows that spectroscopic observations can give us only minimum values for the real speed, and the real size of the orbit But this is not all, the two stars of the pair, as Newton showed long ago, will move around their center of gravity, keeping on opposite sides of it, in orbits of the same shape, but different sizes. The more massive star will have the smaller orbit, and move slower.

With two stars of about the same brightness, both spectra will be visible on the plates—one shifted to the red when the other is displaced to the volet —so that the dark lines appear double, and considerably "washed out" by the superposition of the continuous spectrum of the other star. In such a case we can find the distance of each star from the center of gravity and their distance from one another—still subject to an unknown correction for the orbital inclination.

It is only when the two stars eclipse one another that all uncertainty can be removed. In this case the inclination can be found, the true distance of the stars, and also their actual diameters and their masses. There are about 30 yestems for which this full information is available. Almost all these stars are larger and brighter than the Sun—for the fairly obvious reason that bright stars can be seen at great distances, and have an enormously better chance of getting into our observing lists than those which shine feelby.

How the Spectroscope, Working on a Star Whose Secrets the Telescope Does not Reveal, Affords a Striking Abundance of Detailed Facts

By HENRY NORRIS RUSSELL, Ph.D.

Chairman of the Department of Astronomy and Director of the Observatory at Princeton University Research Associate of the Moun Wilson Observatory of the Carnegie Institution of Washington

They are mostly bot white stars too and again the reason is intelligable. A white star gives out a great deal of light per square mile. If it has a fainter companion of different color and temperature, this will be redder, and have a lower surface brightness, so that, though fainter, it may be as large in diameter, or even larger than its primary. This obviously sets the stage for a conspicuous eclipse, if only the inclination of the orbit is favorable. But if a bright red star has a fainter white companion, the latter will be of very much smaller diameter. If it comes in front of its big associate, it will obscure so small a part of its light that the change is most unlikely to be detected; and when it goes behind, only its own light a small percentage of the total for the pair-is cut off. Hence, even if eclipses occur, they are likely to escape observation, unless conditions are unusually favorable. The remarkable system Zeta Aurigae, in which the big red star is more than 20 times the diameter of its white companion, is one of these exceptional cases

BUT if there is a pair of stars of hearty equal size and brightness, the chance that they will eclipse one another depends only on the orbit sheing nearly edgewise to us, and it should make no difference whether the stars are white or red. We actually find many such pairs of white stars, and plenty of ellow and reddish ones too—but the latter are all dwarf stars of about the size and brightness of the Sun, or smaller.

But cellipsing pairs in which both components are giant stars of low density are very rare. This suggests that it must be decidedly unusual to find a double star composed of two red or yellow guants, and among the far wider pairs, which are resolvable with the telescope, this is the case. Occasionally we find a pair, such as Gamma Leonis, in which the two are of about the same brightness and color. But the great majority of doubles among the giant stars have companions much fainter than themselves. and usually "earlier" in spectral type and whiter in color.

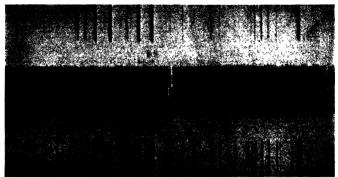

The same thing is found among spectroscope binaries. There are very few giant stars which show double lines, and have companions similar to themselves. Capella is a conspicuous exception, but a rare one. Usually only one spectrum can be seen and we are left with no way of estimating the real size of the orbit or the masses of the stars. Once in a while, luck flavors us.

For example, the third-magnitude star Beta Capricorn—which has a spectrum of Class G, like Capella—was found by Campbell in 1899 to show changes in radial velocity, which later proved to have a period of 1375 days, or 33 years. Only one spectrum was visible. An orbit was calculated, showing that the diatance of the bright star from the center of gravity of the system was 2½ times the Earth's distance from the Sun (plus the allowance for the unknown inclination) and the star was tactify placed on the list of those about which we had found out all we could a superior of the control of the con-

But, in 1935, three new spectra were taken by Sanford at Mt. Wilson on successive nights. These extended farther to the violet than the earlier plates, and showed the great H and K lines of calcium.

Luyten, to whom the plates had been sent, noticed a remarkable thing. The H and K lines in a G-type star are normally very wide and diffuse and very rong. In this star they were weak and shallow, with narrow, fairly sharp lines in the middle. What is more, the sharp H and K lines showed a conspicuous displacement in two days, compared with the numerous lines of the main spectrum.

Sanford then began to observe the star steadily and soon found that these calcium lines shifted periodically in a period of between eight and nine days, it was now wident that this is a triple system. The new lines belong to the fainter component of the system of four year's period, which is itself double, with a period of 8.678 days. It is a much

Courtest The Astrophysical Journal
Two spectrograms of Beta Capricorni (the two-part central area of the Illustration) taken two days apart and adjusted for
coincidence of line detail of star A. Strong K lines of calcium seen at the center of the half-tone belong to star B and are
definitely out of step. The present semispopular acrount is based on the paper by Sanford, published an The Astrophysical
Journal, Volume 89, No. 3. In that journal the American professional astronomer publishes the official accounts of his
researches but, since these are written for the scientist, they often are abstruce and Professor Russell explains them here

fainter than the principal star that its lines would be completely masked by the stronges spectrum of the latter, were it not that these two lines fall in the middle of great wide dark lines in the other spectrum, which afford a "window" through which they can be observed. Three silicon lines belonging to the fainter star (B) and showing corresponding changes in velocity have also been detected in a "window" formed by the strong cyanogen band in the G-type spectrum of star A.

The strength of these lines of sonized whom, and the narrowness of the calcium lines, show that star B must be much hotter than the first—of Class Bs—like Algol. A spectrum extending to λ 2200 in the ultra-volet shows that, in this region, the light of star B is considerably stronger, in comparison with that of star A. This is as might be expected.

No lines belonging to the third body C have been detected. It must be considerably fainter than the second.

If this interpretation is correct, the velocity of the center of gravity of the close pair, BC, should show changes in the four-year period, always opposite in direction to those of star A, so that when plotted they should show a curve of the same shape, but upside down. Sanford's observations have now been continued over almost a whole period and they show conclusively that this is the case. The proof that we have here a triple system is thus completed.

The observations of the wide pair now cover 40 years, and make it possible to

find an accurate period, 1374 days. The orbit has a considerable eccentricity (0.42). The minimum value for the distance of star A from the center of gravity (on the assumption that we see the orbit edgewise) is 395,000,000 kilometers or 2.65 times the Earth's distance from the Sun. The pair R + C is on the other side, at a distance of 360,000,000 kilometers (241 astronomical units) The size of the relative orbit comes out therefore nearly that of Jupiter's orbit about the Sun. As the period is only one third of Jupiter's, the masses must be much greater than the Sun's. They come out 4.35 times the Sun for star A, and 4.77 for R and C combined

(If the inclination of the orbit plane is i, the distance given above must be multiplied by cosec i and the masses by cosec i. For example, if i = 60°, the distance of the star comes out 60 astronomical units and the masses 67 and 7.3 times the Sun's.)

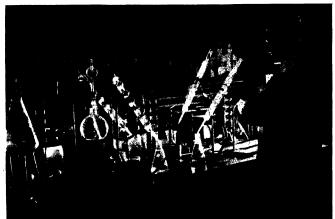

The orbit of B about the center of the pair BC is moderately eccentric (e=0.36) but is small, with a radius of 4,200,000 km. if it is seen edgewise) It can be shown from this that star C is, in all probability, of small mass.

Working, as an illustration, on the assumption that the inclination of the larger orbit is 90°, we have the combined mass of BC 4.77 times the Sun's. For this mass, and a period of 8.68 days, the distance of the components can be calculated and comes out 21,200,000 km. If the inclination in the small orbit is taken to be 90°, C is found to be 17,000.

times as far away as B, so that the mass of B is 4.05 times that of C, which makes 430 and 0.95 times the Sun's. With different assumptions regarding the inclinations, different resists would the inclinations of different assume that the orbit of the water assume that the orbit of the water assume that of orbit of the water assume that of orbit of the water as a small angle, the mass of C always as a small angle, the mass of C always comes out small commared with B.

THIS accounts for the failure of its Indicate the failure of its work relation to appear, for by the well known relation the lumnosity of a star varies about as the cube of its mass (Recent work indicates that the 3.3 power is a better approximation.) On this basis, if h is four times as massive as C, it should be a hundred times as brother.

Comparing A and B, on the assumption already made, we find that the latter has a mass 90 percent as great and should give 70 percent as much light. It appears to be considerably fainter than this; but a moderate and wholly permissible alternative in our assumption about the inclinations of the two orbits would lead to complete accordance The only hope of clearing up this uncertainty lies in the possibility that one or other orbit is so nearly edgewise that eclipses occur For AB this would demand an inclination so very near to 90° as to be highly improbable; for BC the chances are rather better, but the light of A would drown out the variation so that very precise observations would be needed .- - Princeton University Observatory, June 14, 1939.

Equipment for chlorophyll and vitamin research in a biochemical laboratory

Secrets of Life's Colors

NOLORS are clues to life's most fascinating mysteries. Green, red, and yellow --- the most meaningful life-colors -- are guiding scientists through regions in which Nature, by the changing beauty of light waves, signals the locations of treasure caches.

Many of these treasures are turning out to have immediate cash value. Many are discoveries which promise other stores of knowledge that will stimulate civilized progress and some day will alter

the modes of man's existence. Plant green, the pigment chlorophyll, seems to be leading man toward great manufacturing secrets and the ultimate production of both fuels and raw materials as well as foods in almost unlimited quantities. Experiments are beginning to teach man the mechanisms of energy use and fuel production in green plants. Many of the details are already known. When many more are known, then foods, raw materials, and fuels will be almost as cheap as air and water and sunlight. Even now, chlorophyll has practical value. In this country each year thousands of pounds, extracted from leaves, are used to color foods, soaps,

Chlorophyll, Key Substance of Life, Mysteriously Concentrates and Stores the Sun's Energy . . . Gives Promise of Vast Resources to Industry

By BARCLAY MOON NEWMAN

and candles. To medical science, chlorophyll is of inestimable, immediate significance. The architecture of its big molecules is amazingly similar to the architecture of the molecule that runs red in blood.

Green, the prime pigment of the plant world, is most intimately related to red. the prime pigment of the world of animals and men. Study of the one is instructive in the study of the other. In 1931, Hans Fischer, great student of chlorophyll, received a Nobel award for his brilliant synthesis of hematin, the red of animal blood corpuscles. And today the physician is richer in understanding and saves more lives because investigations of green have promoted successful investigations of red-and of diseases wherein the phenomena of

animal red are abnormal and puzzling.

Yellow is as widespread and as important as green, though masked by the chlorophyll of vegetation. A light filter which absorbs most of the green rays from chlorophyll but permits the passage of other light has been devised by the Eastman Kodak Company. A green field or a green forest observed through this filter is a fiery yellow admixed with orange and some slight red. For in every green plant cell there are yellows and yellow tinged with orange and red. When aviators, intent on dropping bombs, observe the landscape through this special light filter, the green of vegetation looks fiery yellow-but the green paint of camouflage still is green, and there is no yellow. Because of this difference between greens-a subtle difference made evident by the filter—and because of the presence of hidden yellow in the one case and not in the other, the bombers know where to loose their destruction. This application of pure science is practical—and of immediate value—if you call war practical and bombing valuable.

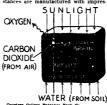

Definitely practical and definitely of inestimably great immediate value are science's new facts concerning these vellow pigments. For, chief among plant yellows are the carotenoids-source of the millions of dollars annually spent to obtain vitamin A, the essential nutrient derived from carotenoids. And who can put a price on the vitality and health that medical science has brought us through its increasing understanding of carotenoids and vitamin A? Certain internationally famed experts, besides, are convinced that vitamin A is one factor in the problem of lengthening the span of human life.

The value of carotenoids to the plant is still unknown, but their occurrence is related to rapid growth and high activity, as in the green leaf, where photosynthesis is under way. Green chloro phyll is never found unaccompanied by these mysterious compounds. Probably their secrets are bound up with the problem of photosynthesis—where chlorophyll has a role of predominant significance.

Green is spread extensively over the earth. This abundance is a sign that the greenness of the chief plant pigment, thorophyll, is indispensable to practically every form of life on this planet. Chlorophyll is an indispensable promote of the transmutation of solar energy into the energy of life activities. Winder energy into the energy of life activities. Winder energy into the energy of life activities, without the energy in the accession oil, and no men. An enlightening and fascinating quiz is to ask a succession of questions tracing back to the origin—the Sun—the energy in the various prominent items of our dietary, fuel, and raw material economies.

PHOTOSYNTHESIS—the synthesis in plants of sugars and other nutrients by the use of sunlight, is almost uniquely interesting as a chemical problem-and almost uniquely complex, too. In this process, the living tissue of the plant absorbs molecules of water from the soil or perhaps a watery habitat. Rays of light energy plunge in from the Sun. The plant uses green chlorophyll to deal with these rays. That is, chlorophyll somehow manages to concentrate their energy and to store it-probably by stimulating the reaction of water molecule with carbon dioxide molecule. The reaction of these molecules results in the formation of sugar and starch, which are energy-rich molecules. Oxygen is a by-product poured out into the airand later becomes the very breath of every creature. If it were not for photosynthesis, the quantity of oxygen in air would gradually diminish and, so runs the evidence, life would vanish almost entirely.

After photosynthesis, by intricate steps sugar is made to yield a vatel list of maternals needed by life. Thus, from sugar, by fermentation in the plant cells, alcohol is made, and afterward participates vitally in the chemical reactions whose sum is life. Sugar likewise is the raw maternal for making glycerine, oils, fats, proteins, vitamins, pugments green, red, and yellow. All these substances are manufactured with impres-

Courtery College Entrance Book Co The green plant cell takes in carbon dioxide and water and, with the aid of chlorophyll (in tiny chloroplast bodies) combines them to make sugar and starch. By-product: oxygen

sive efficiency out of the prime product of photosynthesis: sugar, whose energy came from the Sun and whose atoms once were water and gaseous carbon dioxide. Photosynthesis is the world's most efficient process.

Investigation shows that there are, in fact, two green, having very nearly the same architecture of molecule: chlorophyll c and chlorophyll b. When extracted and crystallized, or is blue black; in alcoholic solution it is greenish black. The solid crystall of b is greenish black; it dissolves in alcohol to a beautiful pure green. Readily as a hanged into b by delicately taking away two atoms of hydrogen and replacing them with an atom of oxygen. The life scientist notes that they are always together in any green plant cell: each is an essential on the result of the scientist can be added to the scientist control of the scientist can be added to the scientist

Each chlorophyll molecule is a web of carbon, hydrogen, oxygen, and nitrogen atoms, with an atom of the metal, magnesium, as a centerpiece and chief feature, when the molecule is taking part in photosynthesis.

The red hematin structure is also a web of carbon, hydrogen, oxygen, and nitrogen atoms, but with an atom of the metal iron as a centerpiece and chief feature, when the molecule is taking part in the transport of oxygen in living things.

To ferry oxygen is the destiny of the hematin architecture. That it makes blood red is a mere happy signal of Nature—not always so eager to help man by arresting signals. The disk-like blood corpusede is red because its activity is the transport of oxygen, and this activity calls for hemoglobin—a giant globin, or protein, to which four molecules of hematin are hitched

The pallor of anemia is another signal, this time of warning, that the body needs more non in its blood, iron in the form of hematin.

Where oxygen is plentiful, as in the lungs, hemoglobin forms a loose combination with it. Where oxygen is low in concentration, as in the tissue deep in concentration, as in the tissue deep in concentration, as in the tissue deep in consistent in the hemoglobin and are absorbed into the tiny laboratories of the cells. There the oxygen is used to burn, to react with, the fuels and release their energy for running the mechanisms of life. These fuels were formed originally in the plant, by the aid of green chloroughly lin photosynthesis, and originally their energy was sunlight. All fiesh is grass, which labors in the sun.

THE iron atom, central feature of the hematin molecule, is empowered to attract a molecule of oxygen—two atoms and seize it, holding at in the web until the appropriate time of release. Thus it he huge hemogloim molecule, having four hematin structures attached, can hold four molecules of oxygen at a time. Each red corpusele, having many hemogloim gainest within its debacet fabric, can carry many oxygen atoms. The transportation of oxygen to the hungry cells far from the lungs as therefore an etherent enterprise.

No scientist thinks that the close likeness of hematin and chlorophyll is an accident One ancient day, when earthlife was young and low in type, live as stance realized the possibility of exclanging an atom of iron for one of magnesium in a web like that of green chlorophyll. Oxygen-ferrying was facilitated. Red blood, and its possessor, the higher animal, could later appear on earth

New discoveries yield striking evidence favoring this theory. Man cannot exist without minute quantities of copper and manganese in his system. These metallic elements, it has recently been found, promote the formation of hemoglobin m factories located in home marrow. And lately, too, it has been found that chlorophyl formation does not take place in the losf in the absence of minute quantities of copper and manganese.

Now color leads us—as it did the investigators of the mystery of life—to one of the major discoveries of science. Throughout all matter that is alive, hematin is found—in the bacterium, in the towering redwood tree, in the aquatic animalcule ameba, in man.

Why, then, is not all living material red? The hematin is present in too low

a concentration to cause any color to show up

Nevertheless, the high sensitivity of the spectroscope sorts that light waves made to pass through live matter and invariably finds those wavelengths which tell that hematin is definitely there, though in proportions almost infinitesimal. Still, distributed however thinly through vital substance, the hematin molecules-we now know-make possible a vastly complex mechanism of energy use. The hematin web is continually busy taking oxygen from this molecule or that, and ferrying the oxygen to other molecules-which then react, usually by uniting with the oxygen, and so are oxidized, burned to release heat or other varieties of energy.

Thus, one great mystery of life is slowly beginning to give up some of its treasures. Oxidation and energy transformations at moderate temperatures constitute a secret not only universal in living things but also thrilling in promuse to man. Cold, white light like that of the firefly and deep-sea monster will be the soft illumination in man's buildings when he solves more problems of the most efficient economy in the world—the physico-chemical economy of animate machinery, which with astoinding ease stores energy in photosynthesis or releases it in physiological oxidation.

SOMEWHERE in the rise of animals, protoplasm learned to put copper in the place earlier occupied by iron in the hematin web, and thus made a blue from a red. The oxygen ferries—that is, the respiratory pigments—of the blood of the octopus, the oyster, and the lobster are hemocyanins and not hemoglobins. They are blue, not red.

Other lines of animal evolution used the red hematin to make their blood pigments and so were able to go higher in the scale of life. Hemoglobin is four times as sefficient a carrier of oxygen as hemocyanin, and is one of the factors in the creation of man out of lower mechanisms. Yet to this day, copper is somehow bound up in the making of hemoglobin

Yellows outstandingly important to life are perhaps most readily seen in the carrot—from which these pigments were first violated, and so called carotenoids. They are vital to the plant and to man—and were the sole source of vitamin A until the eminent biochemist Kuhn recently taught chemists how to make this vitamin in the test tube.

In 1831, ruby-red crystals were extracted from carrot root, and named "carotin." This pigment is now recognuced as a musture of at least three closely related chemical structures: alphas, beta, and gamma-carotene. In solution, the red changes to the yellow typical of disolved or suspended molecules of carotene—as in a number of expension of carotene—as in a number of expension of the egg, in the yellow leaf. But not all plant yellow is carotenoid; not all carotenoids are yellow.

A carotenoid is a special chemical structure a ring of carbon and hydrogen atoms attached to a chain of carbon and hydrogen atoms attached to a chain of carbon and hydrogen atoms. The ring is known as the beta-lonone ring, and holds many a several Chemists first knew it as an essential portion of manya firgratin molecule, such as those min oil of violets. They are surprised to indicate the property of the property of the property of the surprised to learn that it is a vital part of the structure of vitamin A.

Science Service photo
President James B. Conant, of Harvard (right), internationally known
investigator of chlorophyll. (At the
left: Dr. Harvey Cushing, surgeon)

The length of the chain, and the manner in which its atoms are linked, have much to do with the color. Yellow is predominant among these substances, but slight changes in the positions linkages—of the atoms and an increase in the length of the chain yield orange red, and then even reddish violet and very rarely dark blue. The red of tomatices and of watermelons is, for example, a carotenoid—kin of the yellow of yellow to green-macked yellow of all leaves. Vitamin A, however, is colorless—no one knows why.

In the backbowed animal, any one of the three carotenes can act as the forrunner of vitamin A. The liver access to the three carotenes can act as the forrunner of vitamin A. The liver access to the the act of this transforces molecule. And the vertebrate can get no perent ashstance for his vitamin A—no carotenesd —except directly or indirectly from the plant which manufactures yellow. The lack of vitamin A causes lowered resistance to infection, degeneration of akin and mucous membranes, poor vision in dim light, weak dry eyes, and ultimate blindness.

Eggs and milk have vitamın A derived from the animal's ration of plant yellow, or perhaps of cod-liver oil (added to the feed). The cod eats lesser aquatic life, which in turn lives directly or indirectly on sea vegetation which has both green for energy storage and yellow for vitamin A. How intricately woven is the web of life! Bio-science, medicine, chemistry, and eventually even physical (through the study of color's origins) will all amazingly benefit from present and future investigations of yellow, so closely tied up with green and the wellbeing of men with red blood.

The common vellows of fruits, vege tables, and flowers are carotenoids, but there are other vellows. A yellow scarcely vesterday discovered present in practically all living tissues, plant or animal, is vitamin G, or riboflavin, most readily obtained from milk, a rich source and, in fact, until recently the sole commercial source. What rôle this vitamin plays in extending the life span of man is unknown, but the mouse and the rat definitely live longer when plentifully supplied with the nutrient. Until recently, riboflavin obtained by a laborious process from milk was selling at many dollars per gram -- and there are 454 grams to the pound. Thus important did biochemists and medical scientists regard the vitamin. Now, thanks to improved production facilities and commercial synthesis, the price has been much reduced.

THIS yellow takes us back to red. Like hematin, riboflavin is essential to the release and transfer of energy within the vast systems of the life mate rial. It is beginning to appear that in this vellow we have a link between the vitamins and the enzymes, which are the stimulators and accelerators of chemical activities within a living thing. Riboflavin, attached to certain huge protein architectures, endows them with the power to step up the rate of burning and energy- and atom-enchange in many vital chemical reactions. Hence riboflavin, the vellow, is a companion of and co-laborer with hematin, the red, in the control of life's breakdown of fuels.

The world of life is a world of color. And the bo-investigator is finding profound meaning in the play of color. The human eye that looks out over this world is struck by a myriad of clues to Nature's deepest and most significant secrets. And the very eye see by grace of the pigments that signal so fascinatively.

Vitamin A, born of yellow, is a part in of the mechanism of the human retina, and the light-sensitive photographic film, as well as a part of visual purple and other envisual pigments known to exist, but still mysteriously, in the eye's photosensitive mysteriously, in the eye's photosensitive film. The red which vitalizes the brain and nerves and eye is the oflepting of green in the leaf. And throughout the luving mechanism of man, yellow and red are speeding the use of the energy which green chilorophyll helped store during spring and summer. Scientizes find much profit in such thought in such thought find much profit in such thought find much profit in such thought in such thought and the profit in such thought in such though the such that the such that the sum of the sum of

WHAT SIX YEARS DID

In the Design of Large X-ray Equipment, Progress Has been Extremely Great in the Past Few Years... Hospital X-ray equals \$90,000,000 Worth of Radium

AMILJON-VOLT X-ray outfit so small that it can be housed in existing hospital buildings, yet so powerful that it gives X-raduation equulation to several thousand grams of raduum, has been built by the General Electric Company for the Memorial Hospital in New York, where research in the treatment of cancer is being carried on. It is estimated that the radiation from it, based on present-day raduum costs of \$25,000 per gram, will be equal to \$90,0000 worth of raduum.

The new tool of medical research was built following a long period of study with the objectives of reducing the size and cost of very high voltage X-ray equipment, thus increasing its availabili ty to hospitals. The new apparatus can be produced and installed for far less cost, for example, than the well-known 800,000-volt units of 1933 which required a special building to house them and their vast array of supporting and contributing equipment. The 800,000volt unit needed a building 62 feet long, 32 feet wide, and 36 feet high, and many tons of lead to protect operators and patients from the cumulative effects of X rays.

The new equipment consists of a transformer of novel and radical design, together with an X-ray tube built of 11 sections. Transformer and tube are contained in a cylindrical steel tank consisting of two sections bolted together. The total weight, including 1000 pounds of lead for X-ray protection, 4 w000 pounds.

Revealing the filament end of the tube and part of control mechanism

The outside steel shield (left) that encloses the tube and coils

Lowering the 100-coil transformer over the tall and slender X-ray tube

The transformer operates on threphase, 60-cycle power, and is designed to produce I,000,000 volts peak at three milliamperes or more The tube mounted vertically within the transformer in the space normally occupied by an iron core. It is three and one half inches in diameter and 56 inches long The glass portion is completely shudded, electrostatically, for its entire length by the surrounding transformer.

The high tension winding of the transformer consusts of more than 100 thin, flat coals of wire, built like huge pancakes with holes in their centers. These are stacked maide the tank. Through the center passes the X-ray tube with the target end at the bottom and grounded, and the hot cathode filament at the top Completely enclosing the tube and coals is a steel shaded which, in effect, becomes the core of the transformer, although it so on the outside of the coals.

ANOTHER unusual feature of the equipment is that gas is employed as an insulating medium instead of the conventional oil. If oil were used in this unit, about 12,000 pounds would be needed, but only 100 pounds of gas (dichlorodifluoromethane) perform the insulating function

There are no moving parts. The control of the unit is entirely electrical, and the enclosure of the million-volt circuit in a grounded metal tank eliminates the hazard of electrical shock.

Applications outside the medical field include its use in industry, such as for radiographic examination of large steel castings five inches and more in thickness.

Why the Earth's Magnetism?

MAN has known that the earth is be has known anything about magnets. However, scientiats have labored and speculated in vain for over 300 years since that discovery in the attempt to find a reason for its magnetism. Systematic and careful experiments have been made on a scale almost greater than any other scientific project. Special non-magnetic wooden ships have sailed the oceans charting the lines of force. Explorers have carried delicate instruments with them to out-of-the-way places to make careful magnetic meas-

Figure 1. Secular variations of the earth's magnetism, as observed at London since 1540

urements. Numerous stations scattered over the earth's surface have watched the hourly, daily, and yearly fluctuations for many years with extraordinary patience and precision

In the light of this extensive experimental work, a recent paper in the Physical Review, official publication of the American Physical Society, will cause great interest among scientists the world over. This paper, entitled, "On the Origin of the Earth's Magnetic Field," bp Dr. Walter M. Elsasser of the California Institute of Technology, has cast new light on this old problem and possibly pointed the way toward its ultimate solution

Early theories of the carth's magnetism were based on the assumption that the carth is a huge, permanently magnetized hody Such theories would no doubt be very successful if it were not for one serious obstacle. The interval of the earth is very hot, being at least several thousand degrees centigrade, and all permanently magnetized bodies lose their magnetism when they become hot. The only alternative, then, is to say that the earth is a huge electromagnet, not a permanent magnet, and that the magnetThe New Elsasser Theory . . . Radioactivity Heats Earth's Interior, Heat Sets up Eddies, Currents of Thermoelectricity Flow, Causing Magnetism

By C. W. SHEPPARD

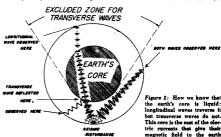

ism is caused by enormous electric currents. These are estimated to be in the neighborhood of a billion amperes. Measurements of the distribution of the lines of force over the earth's surface show that all but a few percent of these cur-

rents must flow in the earth's interior. The remainder can be accounted for by a ring of charged particles flowing around the earth somewhere between the stratosphere and the Moon. A fluctuation of the earth's magnetism in step with the 11-year period of the sunspot activity can be traced to this ring, whose charge dies slowly away only to be replenished by particles thrown from the Sun by the violent eruptions on its surface during the sunspot maxmun

Although a description of the fluctuations of the earth's magnetism would fill many pages, its meet important variations, from a theoretical stand-point, are the long-term, or secular, variations. Not only does the earth's magnetism change gradually over a few centuries under these variations, but also the north and south magnetic poles move around slowly (Figure 1). Any satisfactory theory of the earth's magnetism

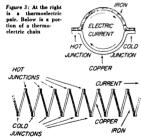

must give a proper explanation of this phenomenon. The fact which makes scientists scrictich their heads the hardest, however, is that, although the earth's magnetic poles are near the north and south geographic poles, they do not concide exactly with these geographic poles. What can be the forces at work which make the earth's magnetism tend to be parallel with its axis of rotation and still allow it to deviate a small amount?

ALTHOUGH our information as to the nature of the earth's interior is somewhat meager, there are good reasons to believe that it is metallic. The most important information on the earth's interior is obtained from the behavior of earthquake waves. These waves are of two kinds, longitudinal and transverse. The longitudinal waves vibrate in the same direction as that in which they travel. Sound waves belong to this class. Transverse waves are those which vibrate in a direction at right angles to that in which they move. The waves one obtains on shaking the end of a rope are transverse. It is well known that liquids will not transmit transverse waves. Observations with seismographs at great distances from earthquake centers show that there is a large core in the center of the earth (its

boundary about 1950 miles below the surface) that does not transmit these transverse waves (Figure 2). Therefore, one can conceive of the earth as a large ball of molten metal with a thick crust of solid material floating on top just as alag floats on the surface of a melting por. It is in this easily conducting core that the electrical currents which keep the earth manutized must flow

Attempts to explain this current as being due to galvanic effects such as produce the electrical energy in batteries have been unsuccessful, for the currents which could be produced in this way would be much too small Elsasser's theory finds a much better explanation in thermoelectric currents. Whenever two metals are joined together, there is a tendency for a current to flow from one to the other This tendency is propor tional to the temperature of the junction and depends on two quantities called the thermoelectric constants of the metals. Unfortunately, it is impossible to measure a current without making a closed circuit. Therefore, one must have at least two junctions Then, however, the tendency for currents to flow at one junction is just balanced by the reverse tendency at the other But, if the temperatures of the junctions are different the effects no longer neutralize and a current flows (Figure 3, top). This principle is used in thermocouples, which have a wide application in measuring high temperatures and in thermostatic control Suppose now that, instead of two strips of the two different metals, we take a large number of strips and join them

in a closed chain so that the two different kinds of metal with their different thermoelectric constants alternate (Fig. 100, Now, if we keep alternate junctions at two different temperatures throughout the circuit, a current will flow in the same way as before where we had only two strips, but a larger one. If a such a situation, or something nearly analogous, could arise within the earth. a. large thermoelectric current would flow. To cause such a systematic alternation of temperatures, the new theory supposes a source of heat at the center of the earth. Given such a source, a turbulent, boiling-up motion would occur. The velocity of the longitudinal waves trans-

mitted by the earth's core, with other information, shows that the interior is very plastic, being somewhat less viscous than ordinary pitch. Thus this boiling motion will be fairly rapid. For the necessary source of heat, small amounts of radioactive material in the earth's interior would be sufficient. This turbulence, or convection as it is called, is the same thing as can be seen in the air above a heater or m a saucepan on the stove This convection will break up into eddies which rotate about an axis pointing radially outward from the center, and the average motion will be in the direction of this axis. Thus at the centers of these eddies large quantities of hot material will be brought up from the interior and cause temperature variations. If then

these temperature variations are coupled with variations in the thermoelectric constants of the surrounding material, a resulting thermoelectric current will be set up.

The question as to how the thermoelectric constants will change is hard to answer. The interior of the earth is at a pressure of at least 10,000,000 pounds per square inch. The highest pressures obtained in the laboratory so far have been only one tenth of this and little hope exists that one can go higher, for the best materials available flow like wax under the stress. However, it is known that high pressure causes changes in the crystalline structure and in the relative composition of various components of alloys,

and that these changes occur

much more frequently than

at low pressures. Since it is

quite certain that the interior

of the earth is made up of several different metals, a large number of these changes may occur, and thus the thermoelectric constant will

However, as it stands, the thermoelectric currents merely cancel out, as there has thus far been no determining factor as to whether they will go from east to west or vice versa. This is where the earth's rotation enters. Suppose a person sits on a piano stool and holds a weight in either hand at arm's length. If he is now set into motion, he will rotate slowly unless he draws the weights in, in which case, he will speed up Figure sketers make use of this principle in the pirouette At the beginning, they rotate

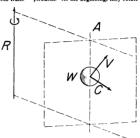

Figure 4. How the Coriolis force operates. The weight W moves in direction V. If whole system revolves around the axis R in direction shown, W will appear to be under influence of a force in direction of C. Direction of C is perpendicular to plane containing A and V

slowly and spread out as much as possible. When they wish to speed up for the spectacular finish, they pull themselves inward. The force which causes this speeding up is known as the Coriolis Force. In general, it behaves in a very complicated manner, and cannot be adequately described without mathematics. However, the effect of it on the eddies maide the earth is to cause them to turn over slowly. Thus an eddy whose axis originally was radial gradually turns so that the axis points somewhat eastward. Actually, the description given here is a much simplified picture, and the real motion will be very complex and irregular. Nonetheless, in the random motion, there will always be the above-described tendencies. Meteorologists are very familiar with this force. since it causes the Trade Winds and the Gulf Stream. In this way, then, the Coriolis Force sets up an asymmetric effect (Figure 4) and a resulting thermoelectric current may flow.

Cartain difficulties are present in the new theory. The greatest disadvantages lie in the imperfect knowledge now existing as to the nature of the earth's interior and the behavior of materials under the enormous pressures and temperatures known to exist there. All estimates of these things are extensions of knowledge obtained in a much lower range and are not likely to be particularly accurate when applied in this manner. But the new theory does provide a start on an old problem.

THE SALUKI EVERLASTING

FARCHING down through the ages comes man's love of hunting as a sport, and the pleasure he took in having about him some reminder of the companions of the chase. In a time when much attention is given to the preservation of trophies by taxidermy, the collection of hunting prints, and to bronze models of champions, ancient man is brought much closer to us when we find evidence of his similar devotion to his hunting dogs expressed in one of his earliest and most personal art forms Such were the engravings of his favorite Salukis hunting hounds on early stone stamp seals

These stone stamp seals were small, thick buttons or disks, sometimes with

knob handles, sometimes without, but almost always pierced so that they could be worn around the neck or attached to the belt by a cord through the piercing. On the flat side was cut some figure or figures which, when pressed into soft clay, left an impression, just as our sealing-wax seals do today. These round, though sometimes square, impressions were men's signatures Later they appeared on clay tablets. Then the stamp seal developed into the cylinder seal which, when rolled across a soft surface, left in the clay an elaborate group of figures and still later carried even the crudely cut letters of the owner's name.

The seals of which impressions are shown at the right are from the joint excavations of the University Museum of Philadelpha and the American Schools of Oriental Research at the great city mound of Tepe Cawra in Northern Iraq near Mosul [Scientific American, Oct. and Dec., 1935 — Ed.] They

come from Levels 11 and 11a and were found in house debrs which is dated before 3500 s.c. The people who occupred the site at this time are called the Painted Pottery Peoples and they have left the stamp of their development in many parts of the Near East by their fine decorated pottery, and at Tepe Gawra by the advanced state of their architectural progress as well. Among the smaller things to play a part Carvings Found in Ancient Ruins in the Near East Show That a Breed of Dogs Now Fashionable Among Fanciers was a Favorite there 5000 Years Ago

By W. H. NOBLE, Jr.

in their lives and which have come down to us, were stone gaming pieces, a pottery holder of an obsidian razor blade (neminscent of our straight-edged razor), superb obsidian bowls showing a patience and technical attainment of high order in working in this stubborn material and, finally, a number of these

Modern drawings of some of the ancient seal impressions or personal "signatures" discussed in the text

small seals of which the impressions of only a few have been shown here.

Crude interpretations of the human figure, geometric designs, fish, and un-identifiable animals appear cut into the faces of the seals, but the one subject, and easily the favorite, in which they exhibit an impressive skill in ortrature, is that of hunting dogs. These tall, alim, and uncommonly graceful animals do not present an easy task to

the stone cutter, yet they are shown standing, seated, or in a playful attitude and you are definitely conscious that with early civilized man's technical ability went a great interest in and love of his subject. On the face of the seal on the opposite page -one of the best preserved of the round seal—there are

as many as three of the dogs and with them are three animals, only one of which is easily identified, an ibex. Of another seal (right, center, in illustration on this page) only a portion of the face is preserved, and there we see the hunting Saluki with a smaller animal in front of him, poorly cut but with the small borns of the gazelle definitely protruding from its head The rectangular seal face in the same illustration presents a nice study in design, with the three dogs placed one above the other. Just what the objects are in front of them it is difficult to say; perhaps they are the heads of a two-horned animal, though these strange shapes may be merely "fillers," for we know that the purchaser wished to get his money's worth and insisted that the engraver fill up every open space!

THERE is no denying the pride which these sportsmen of over 5000 years ago took in their sleek, graceful

took in their sleek, graceful hunting dogs, else they wouldn't have placed them so profusely on what must have been one of their fondest possessions—their stamp seals.

Strangely enough, today in the Near East, one of the Arab's greatest treasures is the same type of hunting dog—the Saluki. He does not, however, actually class his Saluki as a dog! If the modern Arab does not hate dogs, he ranks them very low in his estimation. Nor can he

he blamed, for the usual type of dog in Irak, Turkey, or in any part of the Near East is likely to be a fierce, ungrateful and often cowardly beast-large, dirty, and untrustworthy. Partly, this is the Arab's own fault, due to his had treatment and religious attitude toward dogs. The Saluki, on the other hand, is another matter. He is more lithe and graceful than our greyhound, is larger and faster than our whippet and, above all, is very sensitive to human contacts. An American on one of the excavations in Irak wished to photograph a particularly beautiful example of the Saluki When asked to pose with his dog, the proud Arab master disdainfully refused, denying that it was a dog His insulted dignity could be soothed only when the American photographer obligingly agreed that this was in truth no dog, but an entirely different class of animal-a fleet and noble Saluki.

TODAY the Arab offendi saunters through the bazaars with his beautiful Saliki heade him or smokes his water pipe in the coffee house with lean animal stretched gracefully at his feet. At times be will even bestir himself to hunt the gazelle or the rabit. Then it is that the Saliki shows its greatest critic, its marvelous speed With himsaster riding a horse at a gallop, the Saliki can be seen circling about him in great orbits with unbelievable swiftness, turning in mid-air with a leap when some prey is seented or else spotted with its keen eve.

The actual speed of these dogs is difficult to ascertain, though on Iraki roads one has been known to keep abreast of an American car when the speedometer read 42 miles an hour The driver of the car couldn't "step on it" any more Probably the Saluki could.

In the last few years American interest in these dogs has quite rightly increased by leaps and bounds. There is now an American Saluki Club, and at many of the leading dog shows on the Atlantic seaboard there are classes of Salukis. While their pedigrees are not

Ayesha, the modern Saluki mentioned in the text. She was brought to America by Mr. and Mrs. Charles Bache. Compare with the Salukis on the ancient seals

so old nor in such good order as some breeds, they have been accepted by the American Kennel Club.

The photograph reproduced above is of the famous Ayesha, brought to this country several years ago by Mr and Mrs. Charles Bache, of Philadelphia.

Stamp seals with pierced knobs for

who excavated many of the seals in Irak. Ayesha stands about 30 mehes high and she thought nothing of leaping from the roof to the ground or, for that matter of plunging through a plate glass door in a Beirut hotel, her knowledge of glass at that time being limited. She was entered with notable success in a number of shows in this country, though her parton of shows in this country, though her parton of the same parton of the s

ticular kind was rare, being of a Koweit type. This principality is in Southern Irak on the Persian Gulf and breeds a somewhat more powerful animal.

As we follow the Saluki or his family history down from the Painted Pottery People, interest or evidence of him is fairly slim. In Egypt, on the Old Kingdom reliefs in the Tomb of Tahotep, of the Fifth Dynasty, at Sakkara, we find an animal whose body is that of the Saluki, though the ears are slightly different Here a group is being held in leash by a servant who awaits their mater, while in another register they are shown attacking gazelles during a chase Persian miniatures show him delicately modeled and cream in color, accompanying his belewelled and silken master. Morgan Stinemetz, in an excellent dog chart in Nature (February, 1939), reports that the Saluki first entered England in 1840 but made little headway until imported from Arabia in 1895. After the Saluki's entrance into Russia in the middle of the 17th Century, "to slake a noble's thirst for fast dogs." was crossed with a collie-like native to provide the needed fur and so we have the Borzoi However, this example is a side shoot, not the main line of Saluki descent, and the latter is found in Arabia, not far from the earliest place of record 5000 years old

BUT it is back we must go to that mound of Type Gavra, which flour-ished in the Land of the Two Rivers as long ago as the 4th and 5th Millena a. c., to find men who so loved their dogs that they portrayed them in their signatures and on their amulets, and who deputed them so well that there is no doubt about their descendants in the modern Saluki. These graceful animals bound and prance today. What of their masters?

The ancient seal at left does not look like anything in particular but its impression, shown at the right, reveals three Salukis and some other objects

A MONTHLY DIGEST

Conducted by F. D. Mc HUG H

NEW X-RAY UNITS FOR FIGHTING CANCER

H IGH-VOLTAGE X ray machines of revolutionary design feature the equipment of the Memorial Hospital for the Treatment of Cancer and Allied Diseases, in New York City. Recently dedicated, the hospital uses for radio-therapy a 1,000,000-volt X-ray

Operating one of the easily maneuverable 250,000-volt X-ray machines. These are similar to the 1,000,000-volt unit described in more detail on page 151 of this issue

machine as well as five 250,000-volt unita. Notable for their exceeding compactness and maneuverability, all were developed by General Electric through collaboration among research laboratory sectionists, Memorial Hospital representatives, and G-E X-Ray Corporation engineers.

QUARTZ-LIKE GLASS

An entirely new method of glass manuhacture veiding products which can beheated to cherry red heat and then plunged into ace water without breaking has been developed in the research laboratories of Cerning Glass Works, it was amounced recently by Amory Houghton, President. The Certification of the Complete of the Comcompleted its exploration into the unknown and had established its findings beyond doubt, it will be two years or more before the products can be offered to the public

The weirdest point about the new and revolutionary process is that articles made by it shrink to less than two thirds their original volume yet retain their identity

Contributing Editor ALEXANDER KLEMIN

In charge, Daniel Guggenheim School of Aeronautics, New York University

and suffer no distortion of form. This means a linear shrinkage of 13 percent. For in stance, if you want to make a nine-inch dish you first make one ten and a half inches in diameter.

The new Corning process consists of a series of contrasting operations and there are several alternative variations at the end which give an amazing variety of results In simplest terms, what happens in the main process of this A normal glass object such

Above: Molten iron, poured on new glass chilled by ice, has no effect on it. Right: A 12-inch disk shrinks 1½ inches during processing. The glass is 96 percent silica

as a plate or beaker is made by usual meliing and molding operations but with a special glass formula. Then, through a series of treatments involving final leaching with dulute nitric scid, part of the structure of the glass is removed—leaving a skeleton, so to speak. Then, under further heat treatment, the glass shruks down to a volume which is a reduction of 36 percent from its original size. As a matter of fact, during normal size. As a matter of fact, during of the glass has been removed, 64 percent from the surface feels rough to the touch but does not feel porous. Actually at this stage it is filled with sub-uncroscopic capillares or air spaces. On final heat treatment the glass body reaches a transparent, homogeneous state in which it is practically by percent pure sides. In this completed of the surface of the

The outstanding significance of the new Corning low-expansion glass is that it will offer in an economical price range a material similar to fused quartz. A miniature pilot plant has been operating for several months. To put the process on a full-scale basis would require at least two years, even assuming rapid designing and building, according to the chemists in charge.

PERMANENT GLASS-

CHEMISTS can make an effective and ing equal parts of chrome could with powdered lead borate, and stirring this into a mixture of equal parts of water, alcohol, and glycerin, according to Solvent News. The amount of liquid used depends on the consistency desired.

After applying the ink with a pen and allowing it to dry, the glass is warmed in the yellow flame of a Bunsen burner, then heated to red heat in a blue flame. The

156

glass is finally allowed to cool, using the yellow flame to lower the temperature gradually.

The ink is green, and because of the limitations of the process, cannot be used on heavy cast glass equipment such as desicrators, reagent bottles or the like.

TAXES

DURING 1938 gasoline taxes represented an average of 24.83 percent of all state tax burdens in the 48 states

DESTROYER "HAMMANN" Typifies New Steam

Power Era

THE ghosts of many a windpanner and the wraits of out-model steamships must have looked with enzy upon the U.S. Hammann, news member of the Navy's fleet of destroyers, as she took a "bone in ber teeth" and pranced effortiesly at approximately 38 knots in her hulder's trails creatly assembly the properties of the prop

in Chine da activation of physician value. Sheek and activation of physician da activation of the distribution of the distribu

The story of the Hammans is a story of power, for she is literally a \$5.50,000 power house afloat Compressed inside her needleike bull is power enough to lift the 300,000-ton Goorge Washington Memorial Bridge more than 160 feet an hour-provided of course that the power of her two turbine units could be harnessed to such a task it is the story of the transition of marine

power plant designing from empirical en-

U. S. S. Hammann is an identical sister ship to the U. S. S. Anderson shown above

gineering with low-pressure, low-temperature steam engines to the scientific development of high-pressure, high-temperature turbines based on some 20 years of research. The result is production of destroyers that are the most economical and fastest fighting ships of their are on the Seven Seas.

If judged by appearances, the Hamman is a "little fellow" for a big job, sie's only 341 feet long at the waterline, 36 feet in her extreme beam, and she weight a seant 1500 tons not much heaver than a gun turret on a modern battleship. But encased in her steel shell the ship carriers a compact gover plant that appeardes in performance the tandem turbines built to operate in big city power stations.

The six main turbines on the Hammann weigh altogether only 55 tons, but are capable of producing about 27,500,000 foot pounds of work per second

SMOOTHNESS INDICATOR

A DEVICE so sensitive that it will indicate the differences in thickness of a ingerprint on a piece of smooth glass, has been developed by J. A. Sams of the General Electric Works Laboratory.

Known as a surface indicator, the instrument is used to determine the smoothness of metal or painted surfaces and indicates minute variations far beyond the range of the human eye Variations of as little as 171,000,000 of an inch are clearly indicated.

By its application, the surfaces of bearings or other moving parts of motors and the like, that are subject to wear, may be tested and their smoothness indicated

The apparatus appears somewhat like a phonograph with its turntable on which is placed the object to be tested, and its sapphire-pointed stylus or needle that passes over the test material as it revolves

Small mechanical impulses are created as the hord point rides over surface in regularities. These impulses are then transmitted to an electro-magnetic pickup which converts them into electrical impulses. They are then amplified and transmitted to a recording meter where the surface characteristics are graphically indicated.

The sivins or needle is so sensitive that when it is placed on the revolving metal turntable, the invisible vibrations established by a person whistling are shown on the recording meter.

SOLVENT RESISTANT GLOVES

Eight years old, the Lieutenant de Vaisseau Paris is still in service

bidding, solely, without regard to other considerations. Now, as Chairman Robert H Hinckley points out, much sounder methods are in vogue. He defines the granting of certificates for air routes in the following words. "The law applies the familiar doctrine of convenience and necessity Under that doctrine, in general, an applicant must show that in the territory to be served there is sufficient potential traffic to justify the service, and that the applicant is fit, willing, and able to perform it. We believe that the law requires proof that a proposed operation can eventually develop mail, passenger, and express revenue to the extent of assuring that the new line will not become a burden either upon the government or the community or the corporation proposing to operate it

A mass of new applications is even now before the Authority, with a gridiron of proposed new sirlines. A tabulation of 48 applications from 24 different air services indicates that should all applications be granted, a total of almost 14,000 route miles would be added to the existing system of approximately 35,000 miles. Nothing gives a better picture of the enormous scope of our transport system - A K.

EQUIPMENT FOR SAFETY IN AIR TRANSPORT

WHEN people speak of aeronautical re search they generally mean research in aerodynamics, in the light properties and structural strength of the airplane, in greater engine reliability. Certainly such research is of fundamental importance, and it is also the most fascinating branch of aviation research But, as Paul Johnston, Editor of Aviation, pointed out in a recent paper presented at the Aeronautical Session of the National Safety Council, there is another type of research which is conducted by the airline operators, individually or in co-operation, which is not so recondite, not practiced by mathematicians or physicists, but is of equal importance as far as airline safety is

Thus, in conquering ice formation on the airplane, we find Goodrich continually im-proving its "over-shoes" or wing de-icers. Non-icing carbureters of the Chandler-Groves type are in service and being con-tinually improved by the airlines. Wind-

concerned

shield wipers, with alcohol and other non freezing mixtures mechanically distributed over the windows, is another subject of investigation Improved fluids and methods for protecting the propeller against ice are now available

Radio developments are innumerable, and so well advertised that we need hardly touch upon them here. But there is a long list of other safety devices, some of them of humble character, which may not be as well known to our readers. Thus, upholstery and furniture fabrics in the airplane are being fireproofed Birds have struck and broken windshields time and again; accordingly, windshields are being reinforced. One transport company is testing bullet-proof glass for use in its windshields. The NACA, or venturi engine cowls are being built of stainless steel to withstand corrosion and the effects of high temperatures Cockpits are being improved so that controls can never jam. Hydraulic-pressure bench tests on engine cylinder heads are carried out to warn of possible failure. Metal particle detectors are inserted in engine lubrication lines. where such particles may cause serious damage. Bolts, nuts, and studs on plane or engine may be tightened up too much or too little; instead of relying on the skill of the put into service.

The list could be continued. Any new safety idea is welcomed and investigated if it seems reasonable. Designers and inventors still have a fertile field ahead of them in airplane safety equipment - A K.

FLYING BOATS HAVE LONGER LIVES

W/E have read so much of the achievements of Pan American Airways. with the new Boeing Clipper, in establishing the first north Atlantic air service, that it is hardly necessary to comment further on this historic subject Less spectacular but also interesting is the recent flight of the French flying boat, Lieutenant de Vaisseau Paris, from Port Washington, Long Island, to Biscarosse, France, in 34 hours and 14 minutes. There are two reasons why this flight is of interest. First, it is part of a series of survey flights being made by Air France. Evidently European companies will not leave the field solely to Americans. Second, the Vaisseau Paris is eight years old, and is one of the largest flying boats We used to think of aircraft in the world as fragile vehicles, short lived due to depreciation or obsolescence. The French boat has seen continuous service in various parts of the world, yet is still going strong. Perhaps the day will come when large flying boats will achieve the longevity of the ocean hner - A. K.

SODIUM LIGHTS FOR

SAFER LANDINGS

HEN fog and haze blanket an airport. flight operations may be crippled Radio may bring the pilot accurately to the airport, and a combination of radio and altimeter may bring him down "blind" Still, the average pilot would rather see in the last stages of his flight than trust to instrumenta ion alone Engineers of the Westinghe onse Electric and Manufacturing Company have now introduced a new contact lighting system which holds great promise for operations under poor visibility.

In this new lighting system, three green incandescent lights, placed flush with the ground, indicate to the pilot the beginning of the runway Then, at 100-foot intervals, sodium contact lights of amber color, spaced on each side of the runway, indicate that the plane is over the first 1000 feet or more of the runway. The final 3000 feet of the runway is distinguished by white incandescent contact lights, and at the far end of the boundary there are three more green

Inserting one of the sodium lighting units used as airport markers

lights Such oppositely placed lights mark out the runway in splendid fashion.

Besides the actual arrangement of the lights in relation to the runway, two advantages are claimed. The use of sodium lights increases visibility under foggy conditions. Field tests at Akron indicate that the sodium lights were visible at 410 feet, when incandescent lights were only visible at 35 feet. Again, all the light emitted from the system is at an angle of from zero to ten degrees above the horizontal, so that all the light is emitted in the direction of the pilot's eyes. — A. K.

EXHAUST HEAT TO PREVENT ICING

TCE formation in flight still remains a serious problem, in spite of the strides that have been made in preventing it. A technical note of the National Advisory Committee for Aeronautics states that the Goodrich de-icer (which removes ice forcibly and mechanically from the leading edge of the wing) does not function satisfactorily under some conditions. It has been frequently suggested that exhaust heat from the engine might constitute a fine "ant-icer," and now experiments by the Committee indicate that the idea has possibilities.

the dea has possibilities

A model all-metal wing of six foot chord
was placed in a refrigerated wind tunnel,
in which the temperature was kept at 20
degrees, Fahrenheit, and where a wind
volocity of 80 miles per hour was available.
Natural precipitation was smulated by admitting water to the air stream through a
spray nozile. Electrically heated air was
the through an air duct made the wing,
and a fan was used to circulate the air
made the wing.

The results of the experiment, though prelumnary in character, were satisfactory Jee formation was effectively prevented by mantaining a skin temperature of 200 degrees. Fahrenheit, over the leading 10 percent portion of the wing. The temperature in the duct varied from 300 to 334 degrees, Fahrenheit Heated air velocities in the duct varied

between 45 and 152 feet per second Smalar conditions could be realized by leading exhaust gases from the engine through the actual wing of an airplane. Let us hope that either the Committee or some venturesome engine constructor will carry out a similar experiment in actual hight

No Order of Less than a Million

DOLLARS

TME arplane industry flourished during the World War, almost persibed of manition after the armister, had a boson period in 1929 or thereabouts, and then again fell on very bad times. Now all airplane manitatives, particularly those building military and naval aircraft are flourishing and receiving large orders. It is being and jokingly in the industry that no order under a milion dollars will be accepted. For exmilion dollars will be accepted. For exdistance of the period of the control of the control of the condition of the control of the control of the control of the condition of the control of the control of the control of the condition of the control planes, an example of which is shown in one of our illustrations. Some notworthy items appear in the photograph. The liquid-cooled engine is widenly coming into its own; the familiar radial has disappeared in this ship. Oxygen equipment permits long flights in the sub-stratosphere. Fillets between wings and fuselegs are very large. The vertical tall surfaces are disposed below and above the stabilizer, as a precaution against spinning. The Flot tube for the six-man of the stabilizer, and the stabilizer is the precaution of the stabilizer, as the precaution of the wing and well shead so as to be free of interference. The cockput has perfect vashily All performance figures are withheld,

producing excellent military aircraft.

PETROLEUM

THE fields of Texas, California, and Oklahoma alone have produced more oil to date than have all the fields in Russia.

but it is quite clear that our designers are

LIQUID COAL

DRIVES A CAR

EMBITING the starting possibilities of their nevest development, liquid total, serratus of the five-arch Foundation of Armour Institute of Technology recently showed host basenossible to operate and showed host basenossible to operate and some of the starting of the sta

The most amazing part of the entire demonstration is found in the fact that the test with coal was made on a standard car engine without any changes of any kind in calburction or in the ignition system of the motor, with the exception of the removal of one fine-screen filter

According to Dr Godwin, three different types of colloidal fuel have been used surcessfully in the tests on the stock model automobile to date. The first of these fuelwas a suspension of a specially prepared coal, ground to 300 mesh, in a mixture of gasoline, fuel oil, and lubricating oil. The second test with the "luquid coal" was made with a suspension of the coal in a Dresel oil. The third test was made with a suspension of the coal in a very light oil. The more recent test and demonstration was carried out with a more elaborate preparation of the fuel! A very light oil, or a form of range oil with a light fraction of hydrocarhons, was used as the which; followed by the properties of the coal of the coal of the coal or the suspension of coal of about 500 mels.

Stoking liquid coal in a motor car

In each case, before the liquid coal was introduced into the auxiliary fuel tank on the automobile, it was chemically stabilized in order to hold the coal in suspension

After the liquid coal had been prepared according to the process developed by the secretics, it was introduced into the must yellow the process developed by the secretics, it was introduced into the must per first land. The automobile was then started on gasoline and, after smooth rung conditions had been attended and the motor had "come up to driving heat," the first system was changed so that the gasoline supply was cut off and the liquid coal introduced in the earlier ter. Thereafter the engine zan on liquid coal, and the crareal processing and the starter of superschies.

Although liquid coal is not a product that is ready for the market or, more specifically, ready for consumer use in automobiles, the possibilities as shown by the demonstration are important Especially is this fuel desirable for the home owner who has been concerned with the problem of heating. It was pointed out that this fuel has been used in many types of domestic and commercial oil burners during its development, and that the heat value per cubic foot, as proved by these tests, is considerably more than either coal or oil alone. It was pointed out that the new fuel will make use of the tremendous amount of "fines" which are at present a waste product at the mines - a waste product which the coal producers often cannot even give away

BRILLIANT BLUE

COPPER philaboryanne, one of a new group of synthetic dyes and pegments which was recently deserribed by M. A. Dahlen, of E. I do Pont de Nemours and Company, is a blue dye of remarkable brillance, untorous strength, and fastness. It is replacing rom blues and various base color lakes in prunting inks, and ultramarines in paints, lacquers, and enamels. It is also being used in producing coated and printed testiles, coated paper, colored linoleum, and in rubber to produce any shade

from deep reddish blue to greenish pastel.

One difficult problem solved by the pigment was the provision of a suitable blue

\$12,872,398 worth of these P-40 pursuit planes have been ordered

is easy to nibble and has a pleasant oily

flavor, and includes the following seeds: coconuts. Brazil nuts, almonds, cashews, pis-

tachio nuts, pili nuts, paradise nuts, pine nuts, pumpkin seeds, water-lily seeds, sunflower seeds, and the versatile peanut The pecan nut, produced as a \$6,000,000 per year orchard crop in Georgia and from grown in such quantities that new uses are being sought, particularly for imperfect kernels. Recently, Professor T. H. Whitehead, of the University of Georgia reported to the American Chemical Society what is known of this nut, and suggested industrial uses for its component parts Pecan oil has a bland odor and taste, and, having marked stability against oxidation and even sunlight, has been suggested for use as a salad oil and in cosmetics. Delicious cookies and cakes were made from a base of flour and

necan meal, from which the oil has been

expressed, and development of a similar

Above and below. Two views of the rotury fish screens in the Yakima River, described below, in which paddle wheels turn the cylindrical barrier screens

for three-color printing. Another application is in the production of an exterior paint. The new paint does not have the tendency of previous blue-tinted paints to fade quickly when exposed to sunlight

ROTARY FISH SCREENS GUARD YOUNG SALMON

WORK was completed recently on what is declared by Washington State au thorities to be the largest battery of rotary fish screens in the world, installed across Wapato ditch at Parker, near Yakima. WPA's participation in the project involved supplying the labor, for which \$35,400 in Federal work relief allocations were invested.

These screens were designed to prevent oung salmon, en route from headwaters of the Yakıma River to the Pacific Ocean, which find their way into the huge ditch, from going into the irrigation laterals to destruction

A battery of ten cylindrical screens spans the entire width as a barrier in the ditch. Each screen is 12 feet long and 13 feet in diameter. The flow of water in the ditch turns separate paddle wheels directly connected to each cylinder. Continuous turning prevents the screen from being clogged with mud and debris. By pass channels lead from a bank of the canal, just above the screens, back to the river, to allow the salmon finger-

lings to continue their journey to the ocean. United States Bureau of Fisheries experts and other fish authorities state that the general instinct of the salmon is to return to spawn as an adult to the stream of its origin The Indians foresce even a more happy fishing ground than in generations past, as a result of the fish screens

RUB-LESS METAL

CLEANER

NEW metal cleaner that instantly removes, by chemical action, stains and oxides from chromium, copper, brass, silver, and other metals, has been announced by Rapid Electro-plating Process, Inc., to be sold under the name of "1-Second" Metal Cleaner. It is applied with a brush and immediately wiped off, no rubbing is required

The new liquid cleans hard-to-reach places, does not soil hands, and has no

offensive odor. It is said to contain no caustic; is non-inflammable, will not etch or harm metals; has three to five times the covering power of ordinary polishes, and, since it can be applied with a brush, will clean surfaces maccessible to hand-rubbing

The cleaner can be supplied either with or without abrasive and is designed not only for use in public buildings, households, and automobiles, but also for industrial operations where it is possible to wipe off excess cleaner after application.

BREATH

THE average human being exhales three pounds of carbon dioxide gas per day. To break down this exhaled gas and return oxygen to the atmosphere three large trees are required.

A NUT is an "indehiscent, polycarpel-lary one-seeded fruit with a woody developing from a syncarpous pericarp. Overy " The acorn, hazelnut, and chestnut are true nuts, as are walnuts, pecans, hickory nuts, butternuts, and beechnuts. But by more popular definition, a nut is any hard-shelled seed that contains a kernel that

pecan breakfast cereal appears to be under Industrial use of the pecan is predicated on the success of a new flotation method of separating the kernels from the shells of the cracked nuts, by agitating the mass vigorously in a salt brine, after which the kernels float and the shells sink. This may mechanize an industry hitherto peculiarly dependent upon cheap hand labor. Unfor-tunately, the method recently developed in California for automatically cracking walnuts by miniature explosions cannot be applied to pecans. It will be recalled that oxygen is fed through a cut into the air space (which the walnut alone provides). after which the mixture is ignited by an open flame. [This was described in Scientific American, April 1939.]

The per capita consumption of peanuts The per capita consumption of peanusis about eight pounds per year, in the shells, and the farm value of the crop is around \$45,000,000. The peanut accounts for fully \$200,000,000 worth of business per year in all its aspects. About one fifth of the crop is crushed for oil, and much larger amounts are "hogged off" or other wise used as stock feed. California pro duces \$4,500,000 worth of almonds and \$10,000,000 worth of walnuts annually; and Oregon some \$500,000 worth each of wainints and filberts. Two of the best-flav-ored of all nuts, the hickory nut and the butternut, are not commercially significant, but are the property of the small boys of the

New nuts are added from time to time Out of exotic Hawaii now come limited quantities of the macadamia nut, a delicacy to tempt the palate of the epicure. Cashew nuts were introduced into America not many years ago by an enterprising and imaginative food chemist, who found them in wide use in India. The cashew is a relative of the poison ivy and Japanese lacquer plants, and parts of the cashew plant, if touched, would poison most people, yet the nut kernel, after being Frenchfried in hot fat, is a delicious tidbit, notable for its tenderness and sweetness While at present the cashew nut is being exploited almost entirely as an edible nut (30,000.-000 pounds per year of the kernels are consumed), the shell contains a substance which may eventually become more important industrially than the kernel itself. his substance is a resinous liquid which, when chemically treated, forms products which are of marked utility in the plastics

The almond is practically a nofs-shilled practisation that has a pleasing high-proton kernel. Few other muts have more than 10 or 15 percent of proteins, but contain from 40 to 75 percent of fast and small amounts of starch and sugar. Pecan meats are the richest in fat of all nut meats, with Parzil nuts, filters, and walusts not far behand. Nuts are a highly concentrated behand. Nuts are a highly concentrated worson. 8 commercially good source of the votame 18 commercially good source 18

The coconut tree is credited with being by far the most valuable of all the food trees of the world, and is of vital importance in the tropics. The prosperity of the South Sea Islands rises and falls with the demand for copra, or dried coconut meat, which is the source of coconut oil. This oil is used in immense quantities for soapmaking and in oleomargarine, and the resiiue is valuable concentrated cattle food Because of excise taxes placed on such oilbearing nuts as the coconut and palm kernel, other nuts with strange names are finding a large North American market. In this group are the babassu nut, the cohune nut, tucum nut, ourscury nut, and the murumuru nut, all South American .- The Industrial Bulletin of Arthur D. Little, Inc.

WOOL

TWENTY-five million pounds of wool, the product of 3,000,000 sheep, are consumed by the automobile industry in an average year.

DIGESTIBILITY OF

STRAW

STRAW contains large quantities of carbohydrates which can be only partially digested by farm animals. Various attempts have been made to increase the digestibility of straw by some pre-treatment.

In the course of an investigation of the problem, oat- and wheat-straw were treated with caustic-soda solutions of varying strengths and for varying lengths of time.

Best results were obtained with a 1.25 percent solution and an immersion period of 20 to 24 hours without heating. With

BURIED TREASURE FOR THE 70TH CENTURY

by Westinghouse

Many people have asked us how the Westinghouse World's Fair Time Capsule came into existence. Why should an electrical company be so interested in what the people of 5,000 years hence think of us?

It all started with the slogan of the New York World's Fair. Most people, we knew, were thinking of "The World of Tomorrow" in terms of ten or more years. Why not, somebody suggested, take a real leap into the future?

Groups of scientists, to whom we appealed for advice, applauded the idea of preserving something for the future; said it was too bad the Egyptians, and the Sumerians, and the Mayas hadn't been as thoughtful. Librarians, printers, historians and others helped with suggestions for the Book of Record of the Time Capsule, which is expected to preserve the story of the Time Capsule for future generations. A committee of engineers decided that one of the newest alloys, Cupaloy, could be counted on to resist corrosion, pressure and other hazards for many thousands of years. By using the latest techniques, such as microfilm, we were able to cram an astonishing lot of information, and several hundred articles and materials of common use, into the Time Capsule.

Through it all, we had the help and enthusiasm of many of the country's foremost scholars and scientific men. In fact, it was an illuminating experience to learn how pleasantly men and women in all walks of life can cooperate in the working out of a simple, uncommercial, imagination-provoking idea. It was an emotional experience, too. On the day when the Time Capsule began its long rest, at the site of what is now the Westinghouse Building at the New York World's Fair, more than one person in the audience wiped tears from his eyes when the glistening Cupaloy Capsule began its solemn descent.

But what's the nub of it? Well, we think the Time Capsule attracted such wide and kindly interest because it is a sort of symbol of our age; an age of which most of us are intensely proud in spite of many difficulties and shortcomings. An age that not only believes it has something of great value to preserve and pass on to the future, but equally significant, one that knows how to preserve it—at least the material part of it.

We hope the "futurians" do find the capsule, of course. If they are so far advanced that the objects we have left seem only toys to them, we think they will nevertheless be interested to know that an age otherwise pretty intent on its own problems, still found time to think of the future.

Old and New; Spiral paper (top) and new molded pulp wire insulation

the volume of solution used, this represent ed 10 pounds of caustic soda per 100 pounds of straw. The starch equivalent per 100 pounds of straw was more than doubled by the treatment

CLAY FILM

SUBSTITUTES FOR MICA

DEVELOPMENT from common tlay of a film which looks like celluloud or Cellophane and which can be stored in water for an indefinite time without determinating, was announced recently at the Sixtenth Colloid Symposium of the American Chemical Society, a Nanford University, by Professor Ernst A. Hauser of Massa Invests Institute of Technology and Miss D. S. le Beau of the Dewey and Almy Commany.

In sheet form, the new material, Professor Hauser declared, promises to supplant sheet mica, a strategic military material, important in insulation, which the United States has to import from foreign countries in thousands of tons annually.

The water-resistant quality of the nex thin as the result of research us completed, Professor Hauser said. The first self-usyporting, otheren sheets made from pure clav about a year ago swelled and finally distingrated in water. Called "alsoffin," in," qualities, according to the chemists. Being entirely composed of morganic maiter, it was non-inflammable and would stand extremely high temperature without decomposition. It was resistant to oil and

organic solvents in general, as it basically contained aluminum or magnesium silicates. In dry condition, it exhibited very satisfactory electric insulation properties, which, however, dropped rapidly as soon as the film picked up traces of moisture.

The new water-resistant film overcomes this drawback and retains all of the good qualities of the first clay film. Both in regard to its general properties and its actual composition, the material, Professor Hauser pointed out, is comparable with mica.

The alsifilm can be produced in any desired size and thickness and can be made decidedly more flexible than natural mica

RAILROAD TRUCKS

AMERICAN rullroads have 53,000 motor trucks in terminal transfer, inter-rity, and store-door delivery service. This number of trucks exceeds the number of locomotives operated by the railroads.

Since the machine will record ordinary conversational tones within a radius of 20 feet, it is possible to record a business conference or discussion participated in by a roomful of men.

At nowapper offices, with the personnel buy, the machine may be hooked up to the telephone to take down stories phoned in by reporters, saving the stengerapher and obtaining an error-proof record. In hostopital, with the aid of ear-phones, a patient may be read to sleep without disturbing others in the same room. Foreign languages and musle may be taught by mail with the same efficiency as personal contact. The actor can hear himself as others hear including the same officiency cards, by recording wice plictures on the spot of the wonders he is eseing, and mailing the letter forthwith.

GERMICIDE PROTECTS SPORTING EQUIPMENT

THE problem of storilizing and deodorizing sporting equipment long has troubled proprietors of skatling rinks, symnasia, and swimming pools. Taking a tip from the WPA., many now are using Wyandotte

Steri-Chlor, an effective germicidal agent that may be applied in powder or liquid form. Experience of the federal government has

proved that this product is excellent for dis-infecting boots that are worn by many work-ers. A half-teaspoonful, sprinkled inside each shoe, retards the spread of athlete's foot and umilar diseases

The product is stable and will maintain uniform strength. When used in solution, its low temperatures, providing the highest degree of sanitation.

Because it harms only germs, it is widely used in sterilizing fountain and dairy equipment. This fact also recommends its use for protecting all types of sporting goods.

PLASTIC COMPOUND FROM

SUGARCANE BAGASSE

PLASTIC compound made from the A lignin and cellulose of sugarcane bagasse, one of the country's important agricultural waste products, has been manufactured by chemists of the United States Department of Agriculture at the Agricultural By Products Laboratory, Ames, Iowa. The

Sugarcane bagasse plastic may be molded in a wide variety of forms

can be manufactured for less than half the cost of the cheapest synthetic plastic compound now on the market.

Molding compounds may be made from the bagasse by three methods The first, and cheapest, is hydrolysis with acid. Counting the cost of bagasse at eight dollars a ton, baled and delivered at the factory, the chemists estimate that a plastic compound can be made by this method, in which the cost of material will be slightly more than two cents a pound. Plastics made from the compound, while not so strong as some synthetic products now in use, are quite moisture re-sistant and would be suitable for molding bathroom tile for both floors and walls. They apparently have the wearing ability of wood and may be sanded and re-polished through the entire body.

The second method is hydrolysis in the presence of aniline, a coal tar derivative. The material cost of plastics from this proone material cost or plastics from this pro-cess will be more—about 4½ cents a pound —but they are as strong as plastics now in use. In tests it has resisted bending pressures up to 9000 pounds per square inch. They are slightly less water-resistant than plastics made by the first method, but do not warp

and may be sawed, drilled, and, with care, nailed. These properties suggest uses as card table tops, desk tops, and building panels

Treating the bagasse with sodium hydroxide and furfural is the third process. In quality, plastics from this method are about midway between the other two. They flow better and mold at 2500 pounds per square inch compared with 3500 for the second treatment. They may be put to the same uses as the plastic from the second treatment.

Either of the plastics made from the last two processes do not shatter easily. In fact, neither breaks when struck hard enough with a hammer to cause a dent.

It is possible that other farm waste materials, such as corn-talks and straw from small grains, may be used in making plastics by the same processes, the chemists report.

TOLL

DURING 1938 in the United States there was one accidental death every 5½ minutes. Non-fatal injuries suffered in accidents occurred one every 3 seconds.

Indicious liggles

VIBRATION is like a silon steak in on the hast of can be one man's meat or an other than the can be one man's meat or an other than the can be one man, and the can be of the can be under the can be under the continuous control. There are numerous nonts in industry, notably in the fields of construction, mining, chemical processing, and conveying, where a little judicious processing, occlares the Industrial Bulletin of Arthur D. Lattle, Inc.

When these vibrating tools are electrically operated, the source of power in generally a magnet, for it lends itself to mechanisms which are simple in construction, with few oiling points, and with correspondingly few points to wear or cause trouble. The ruggedness of such tools is indicated by the fact that a large outlet for them as in ham-electrical method offers awings in weight and freedom from auxiliary cultiment.

and irecdom from auxiliary equipment. The conveyor him is a frequent user of magnetically induced vibrations. Not only ill relatively furcation metarials like sand trough, but also obdurate objects such as dog biscusts or metallic fasteners which, under ordinary conditions, may not "flow" at all. Although the eye sees only a uniform progression, the goods are actually jumps. (The dog biscusts—and articles less inherently humorus—will move as steadily up a slight incline as they will on the level, and withston conveyors are often so level, and withston conveyors are often so

By means of a rheostat, the rate of feeding can be varied from, say, 10 tons per hour, as in one application in a smelling plant, to a slow dribble. Vibrating conveyor feeders are particularly useful in conjunction with automatic weighing devices, because the close control possible allows an operator to feed rapidly until the scale beam trips, then to stop the flow of material instantly In spite of the wide use of magnets in other fields and the accumulation of much empirical data, there are no comprehensive formulas which permit the ready calculation of optimum dimensions for a given condition. Experience during the past decade, therefore, has led to steady improvement in details and to the exertion of progressively greater forces for the same movement of the magnet armature. A more hasic improvement has been the applica-tion of "power pulses" to energize the magnets Engineers attempting to avoid vibration, strive for a smooth, steady flow of power through their apparatus, builderof electromagnetic vibrators want, and have obtained, power that comes in spurt-The simplest way to supply the magnets with oversized "quantums" of energy separated by periods of no current flow is to use so-called half wave rectified alternating current (produced by passing alternating current through some electrical valve that allows current moving only in one direction to pass through it)

A recent and important advance is the use of pulses created by condenser discharges, a method that allows great flexibility in the frequency at which the pulses are supplied Developments in large capacity electronic tubes permit the original source of power to be either alternating or direct current, and in this manner make control of the condenser discharges commer cially feasible

The icy permanence of print makes the prediction of applications for this increased versatility a dangerous pastime, but magnets are already shaking screens in many proce and mining industries. Electrically vibrated screens have been found particularly resistent to "blinding" or wedging of the material between the wires

Vibration is necessary in making pulp fibers mat into a sheet of paper, it is also being used in the placing of concrete. Satisfactory consolidation can be obtained with water-cement ratios than is practicable with hand-placed mixes, and physical properties are correspondingly better Artificially induced vibration has even roved to be a valuable means of testing laboratory specimens and completed structures such as bridges, buildings, and water tank towers. Oscillators are attached to the structure, and measurements are made of energy input and the degree of dampening. From the readings can be deduced such dynamic properties as endurance limits, periods of resonance, and the existence of structural defects.

In these cases, as in most others where vibrations are deliberately created, no random shakes will do, but it is necessary to provide oscillations which can be adjusted to meet variations in the conditions or to give optimum results.

COPPER-BEARING CEMENT

COPPER-BEARING cement, recently A announced, appears to have possibilities of great usefulness in making "composition floors, stucco, and mortar for tiles and glass brick, reports Highway Research Abstracts.

Finely divided copper incorporated with "caustic" magnesia (not the dead-burned MgO) and mixed with a solution of magnesium chloride, produces in the mixture a

synthetic mineral that has good resistance to weathering. Thus compounded, the prod-uct possesses the advantages of flexibility, resilience, and adhesiveness without the disadvantages of poor weathering, efflorescence, and incompatability with lime.

Strength of the cement is high-several times that of Portland, The two materials do not compete, however; the copper-bearing cement, because of its higher cost and high heat of setting, is not intended for massive work, it supplements Portland cement.

How admirably the cement supplements and complements other building materials is indicated by a statement of some of its properties and uses It is not damaged by water It bonds perfectly with a great many sub-stances; for example, its adhesion to sandblasted glass is more than 100 pounds per square inch It can be troweled, brushed, or sprayed into position. Setting is very rapid As a masonry paint it allows the material underneath to "breathe." And it will take almost any kind of filler or aggregate sawdust, marble, asbestos, or what not.

FUEL

THE giant turbines of a luxury liner use almost 32,500 barrels of fuel oil on a transatlantic crossing.

MIDGET MARINE RADIO TELEPHONE

FOR the safety and convenience of those thousands of yachtsmen who put out to sea in small boats, the Western Electric Company is introducing a low priced, midget marine radio telephone so simple to operate, so reliable and small, that it may be com-

pared with the familiar telephone ashore The little instrument is designed to link those aboard the craft with the telephone system on land, with the Coast Guard, and with other radio-equipped boats.

To make a call with the new instrument. the user merely turns an "on" switch which places the equipment in operation, presses "talk" button contained in the handle of the handset, and gives the telephone operator the number desired. Calls coming from shore, or from other boats, are signalled by a loudspeaker contained within the instru-

ment. The loudspeaker may be switched off during the subsequent conversation.

uaring me subsequent conversation. Provision may be made also for "selective calling." A hoat so equipped is assigned a number, and its equipment maintains a continuous, silent watch, to receive only calls that may be directed to it. When the short station operator dials its number, a telephone bell rings exactly as on land.

Built in a single self-contained unit, and cuspared to coupy less apace than a small overnight bag, the instrument is easy to install. Rather transmitter, receiver, power conversion pack, and built-in loudspeaker are all assembled in a special metal cahnier that a lia finished to resist corroson, and only three electrical connections are required for installation: the antenna wire, ground, and power supply.

The dence may be operated from a suror twelve will battery or it may be simply adjusted for use with other voltages. The transmitter operates on any one of four crystal-controlled frequencies. By merely changing the quatry plates, frequencies other than those originally selected for the transmitter may be substituted, within the trange other in the control of the control of the transmitter of the control of the control of the control of the control of the transmitter of the control of the control of the control of the control of the transmitter of the control of the control of the control of the control of the transmitter of the control of the cont

Specially trained personnel is not required to operate the equipment. The regulations of the Federal Communications Commusion permit the operation of radio telephone equipment in marine service by persons holding a thrift class radio telephone operator's incense which calls only for an elementary knowledge of the radio laws and regulations, and familiarity with the method of operating the equipment.

PAINT ON A WATER-BEADED SUBFACE

O RDINARILY, paint must be applied to a dry surface to furmsh a satisfactory and permanent finish. This rule need not always be followed, say the manufacturers of We-K-Hale paint. They claim that their product will adhere perfectly to wet surfaces, as well as dry, and will eliminate the need for temporary shutdowns or materiphic not working flours date to wet

The manufacturers state that the mate-

NEW STEAM

POWERFUL steam generator no larger than an incandescent lamp, and similar in appearance, has just been announced by the Westinghouse Lamp Division, Westing house Flectric & Manufacturing Company With a thermal efficiency of 90 percent be cause the heating coils are directly immersed in water, this flash-type of heater can generate superheated steam from cold water in less than 15 seconds It is made in 1000, 1500, and 2000 watt sizes, with evaporating capacities up to 57 pounds of water per hour, and can superheat steam to 350 de gress, Fahrenhen

The cylindrical case of the diminutive steam boiler, 91/4 inches long over all, is made

Midget electric boilers generate steam after 15 seconds of operation

of transparent glass, capable of withstanding an internal pressure of 25 pounds per square inch It is provided at one end with two heavy electrical terminals, sealed directly into the glass. The chemical-resistant glass is capable of withstanding mechanical stress and will also withstand being transferred instantaneously from cold to boiling water, or vice versa, without cracking. A threaded pipe is sealed into the opposite end of the envelope as a steam outlet. Resistance wire coiled on an insulating core occupies most of the interior of the heater, leaving, in fact, space for but five ounces of water at

The generator may be used for many purposes for which either no steam supply has been available or where the economy or convenience of the new method of steam generation is outstanding. The steam generated by the new device may be used for the sterilization of dishes, glassware, instruments, utensils, clothing, cloths, toilets, and furniture. It may be used in the process of steam distillation often necessary in chemical laboratories and in small chemical plants. It will furnish a convenient steam supply for pressure cookers and small steam ovens, and can be used to supply industrial

A PROBLEM FOR THE MATHEMATICAL READER

A FARMER tethers his cow to a stake driven at the edge of a circular pasture, 200 feet in diameter. How long should the

rope be if the cow is to be allowed to graze one half the area of the field?

This problem is offered by Lieutenant Commonder Leonard Kaplan, United States Navy, to readers who enjoy wrestling with things mathematical. No prize is offered for its solution. The correct answer is 115 87 feet but the solution—which is the part having chief interest to the mathemati can—will be published in this department next month.

Institutional Commander Kaplan was the author of five problems offered in our April, 1939, number, page 219. The answers were given in the same number, on page 251, but the solutions were not published because they were so long. The solutions to the above problem is not so long and will be published in the meantime, please address all correspondence regarding this problem to Leutenant Commander Leonard Kaplan, in New York, N. Y. and it will be forwarded unoppened.

steam for other small-scale processes. Used as a still, it could produce on short order limited supplies of distilled water for drinking, for garages in isolated places, or for medicinal purposes. The generator can be used to raise the temperature of water to boiling, for diskwashing or for general use as a domestic hot water supply in dwellings.

To REMOVE SILICA FROM WATER

MOST natural waters contain silves. Which, if the water is used for boiler feed purposes, may react with any calcium present to form a hard deposit of calcium silicate. If the silica content of the water can be kept below five parts per million, the possibility of its concentration and subsequent precipitation as silicate scale is greatly reduced.

Data recently published by the National Aluminate Corporation indicate that silica may be removed from water by treatment with hydrous aluminum oxide and that the oxide may be prepared from sodium aluminate. It was also found that pH control is necessary for optimum results.

KID PICTURES

DICTURES of children know no seasons. They furnish one of the most stable subjects in all photography In any mood, at almost any time, children are "available" for picture-making and need little urging, if any. The matter of dress, too, is hardly of any consequence, their mothers to the contrary notwithstanding. In fact, "dressing up" the children for picture-making is one of the chief problems the photographer has to combat Not only subjected to these embellishments, but they fail to behave naturally, with the result that the picture is, in some sense, a failure, no matter how good it may turn out to be technically

So take your kid pictures when, as, and if the opportunity occurs for unusual shots.

"Gee"

Move close for pictures of children in order to reveal their childish expressions. Avoid contrasty or low-key lighting as much as possible. Don't worry about freckles or lost teeth, but make the most of them. Get them candid-wise or let them pose themselves naturally, in the latter case perhaps aided by a hint or two from you. Babies will give no trouble in this regard because they don't know what you're about anyway.

Don't spare film when the kid shooting is good. Although occasionally you will get just the right expression and pose the very first try, the chances are that you will have to take several in order to afford a selection later on. Any camera will serve the purpose and the use of the enlarging

"Little Miss Homebody"

process will make up for any lack of ability to come closer with your particular lens equipment. Where it is found desirable, some diffusion under the enlarger will frequently help to improve the result by softening sharp outlines. Watch out for good backgrounds when you can, but since you cannot always choose, it may sometimes be necessary to shoot against a disturbing background or not to shoot at all. Such a picture as "Gee!", for example, either had to be made as it was or be lost altogether. Illustrating this piece are a few pictures of children made on different occasions.

"State"

"If1, there!" was one of those impromptu things that make the photographer's life a happy one. While we were idling with the camera towards the end of a busy picnic day, a mother and her baby, friends of our group, came along to join us. As they re-clined on the grass conveniently only a few feet away from the camera, we shot head on from ground level just as the baby was exchanging smiles with someone standing back of us. The pose of the mother's head as well as that of the baby, together with the animation expressed in both faces, seemed made to order.

A week-end visit with friends produced "Little Miss Homebody." One of the secret objectives of the trip was to make a picture of the little daughter of the couple we were visiting, but she was an extremely active child and we had almost despaired. Finally, just as we were about to leave on a few hours' auto jaunt into the country, she sat down in a big chair by a window There was not much light coming in, but opportunity was knocking and we had to make

"Pals"

the best of things Setting the camera on the window sill to steady it and asking the subject to hold still "for a second" we hararded a shot at 1/5 of a second, f/3.5 lens opening. The negative showed the hands sharp, but the head had moved slightly. The expression and the pose were so charming it seemed a pity to lose the picture just because of a little movement of the head The solution came in the use of a diffusion lens during enlargement. This effected the desired compromise between the sharp hands and the "soft" face definition, besides affording a pleasant and desirable atmospheric effect.

"Susie" was also enlarged by diffusion. this time in order to minimize the harshness of the high-lighting as well as to assist in reproducing the mood of the subject at the time the picture was made.

"Gee!" was another picnic shot and was ne of a group we shot "from ambush." The boy knew the camera was present but appeared to ignore it. At the particular moment this picture was made, he was listening wide-eyed to the sound of an air-plane passing by. The person sitting by him moved back quickly so that while the background is somewhat cluttered up, the boy's face and figure predominate. If there were more lessure time than we have at the moment, the paper negative process could be profitably employed in removing most of the objectionable background

"Pals" was shot against the clouds from an extremely low position. More of the figures was included than shown in the picture, but cropping under the enlarger enhanced the effect by bringing the faces into greater prominence.

HAVE YOU TRIED CONTRAST FILTERS?

DARK sky standing out in stark con-A DARK sky standing out in stark con-trast to white clouds is not true to nature, of course, but there is no doubt as to its pictorial effectiveness. The yellow

PRIZES

E VERYONE who owns a camera
has a chance of winning a valuable prize Plan now to enter your prints in this contest. You may enter not more than two prints may be en tered by one contestant in any one of

Specific rules for this contest are pub lished below Be sure to read them

RULES of the Contest

- 1 The groups will be judged independently on the basis of pictorial appeal and technical excellence. The decision of the judges will be final. In case of a tie for any prise, duplicate prizes will be awarded to the tying contestants
- 2 Prints must not be smaller than 5 by 7 or larger than 11 by 14 Prints need not be mounted, but may be at the contestant's option
- Photographs must be packed properly to protect them during transportation
- 4 Non-winning entries will be returned only if sufficient postage is included when the prints are submitted
- 6 Each entry must have the following data written on the back of the print or mount Name and address of contestant, type of camera, and film enlarger and
- 6. Contestants may submit no more than two prints in each group, but may enter any or all groups
- 7. Prints must be in black and white Color photographs are not eligible
- 8. Prize-winning photographs will become the property of Scientific American, to be used in any manner at the discretion of the publisher
- 9 Scientific American reserves the right to purchase, at regular rates, any non-winning entry
- 10 No entries will be considered from
- 11 All entries in this contest must be
- in the hands of the judges by December 1, 1939 Results will be announced in our issue dated Fabruary 1940 12 This content is open to all amateur protographers who are not in the employ of Scientific American

medium filter is still the most useful and the most convenient for the purpose. All we have to do is double the exposure or open the lens diaphragm one stop larger than would normally be required without the filter. But a deep yellow filter, requiring only three times the exposure, when using panchromatic film, or an orange, requiring about four times, or a red, calling for six to eight times normal exposure, will provide more dramatic sky backgrounds, though at tage of using these contrast filters is the relatively long exposure required, but in these days of very fast film emulsions, snapshot exposures may be had even when using red filters.

FOR THE NATURALIST

WHAT'S wrong with this picture of snake's eggs? One person tells us the eggs look very large when as a matter of fact they were quite small, roughly a little under 2 inches in length Some fa-

"Snake's Eggs"

miliar object, preferably a pocket ruler, should have been placed alongside one of the eggs to indicate its true size, or a human hand might have been included in the view, picking up one of the eggs or holding it in the palm. The picture was a snapshot at close range, employing a supplementary

ADAMS INSTITUTE

NDER the personal direction and instruction of Dr. Richard Bettini, Dean, whose family has been actively associated with photography during practically the en-tire century of photography's existence, a new school of photography has just been inaugurated in New York City under the name of the Adams Institute. Dr. Bettini's grandfather entered the photography profession in 1859, being later succeeded by Dr. Bettini's father. Many internationally famous persons have been photographed by the three Bettini's, including royalty, arists cracy, Popes, Cardinals, and persons high in artistic and other quarters.

Equipment of the school includes an unusually large darkroom furnished with 18 enlargers and other equipment which represents a wide diversification of various types of facilities "so that an individual will have an opportunity to work with and com-pare the different apparatus on the market." There are three sessions daily morning, afternoon, and evening - each session lasting four hours and continuing for a period of two weeks

BALLYHOO PICTURES AT THE FAIR

THE Amusement Area at the New York World's Fair is rich in human interest possibilities Among the most attractive subjects are the barkers at work. Night shots are usually more striking than those

"Ballyhoo"

made by day because of the more interesting lighting. Fast pan film should be used Exposures at 1/25, 1/50, and even 1/100, depending on the lens speed, are sufficient to record all necessary detail Move in towards the front of the crowd in order to avoid obstructions and to get a clear view of the subsect

LEICA 25 YEARS OLD

IN this, the 100th year of photography's existence, Leica celebrates its 25th birthday With more than 300,000 Leica cameras in use throughout the world, the Leica people recount this camera's achievements the first to introduce the 24 by 36mm negative size, using 35mm motion picture film; the first to use a collapsible lens mount for compactness, the first to couple the film advance mechanism with the shutter rewinding mechanism; the first to apply a range finder to photography, the first to couple the range finder with the lens for automatic focusing, the first miniature camera to utilize interchangeable lenses, and the first to apply universality of operation to a camera by making available accessories to extend the scope of the instrument

THE NEW CAMERA

THERE'S no use going against nature. The most plainly worded instruction book will be half read, if at all, in the enthusiasm of that first period of ownership of a new camera. We are so eager to start shooting pictures that we lose all patience with the hard fact that we should learn

CAMERA CROSS ROADS OF THE WORLD

how the camera is operated before we start using it. This department would like to suggest that manufacturers and distributors issue two sets of instructions, one extremely brief and giving only the bare essentials necessary for operating the camera, the other more extended and detailed. The brief one would be for use in the first moments of possession of a new camera and would be written in monosyllabic language, just as one would give instruction to a child. Best of all, the dealer should load the camera for the purchaser, set the distance and stop for fixed focus operation, instruct the user to shoot only in broad daylight, and show him where the release button is After the first roll has been exhausted, the new-camera owner may come to his senses at last and decide to cut out the foolishness and get down to brees tacks

BALANCING THE ANGLE

MEN at work frequently offer striking subject-matter for picture makers, and one of the best viewpoints to adopt for unusual pictures is that of the up-angle. In the present illustration, the men were suitably placed for a good composition. The diagonal was inevitable, but it was necessary to wait for the standing man to get into the position shown before the picture

"Men at Work"

could truly be said to have balance. This balance is facilitated by the fact that the man's body is slightly tilted forward. Unity is achieved, too, by the fact that both men are engaged on one thing and are facing towards each other. A filter was used for the sky.

THAT DOUBLE CHIN

OCCASIONALLY you will be confronted with the problem of how to minimize or to some extent avoid representing the double chin of your subject. This is par-ticularly a problem with women. In moderate cases, a shift in the angle of the head is all that will be necessary. Have the subject seated facing on an angle with relation to the camera and then turn her head to-wards the camera. Caution must be used here, however, to prevent too many folds in the neck, which might prove almost as

it in AMERICAN

that is inclined to our somewhat. A still easier method and one that will leave the print clear of marks to the very corners, is to use double-sided adheave. This is available in a product known as Twintak. Cut four short strips, remove the linen fabric that covers one of the adhesive sides, and attach to the under side of each of the four corners of the paper Then place the paper in the desired position on the baseboard, after having previously focused on an ordinary sheet of paper in the usual way, and the paper will stay put wherever placed.

CLEANING OLD PRINTS

HERE is a professional tip that many amateurs can put to good use Onc photographer who occasionally has to re vive an old print which has become soiled for one reason or another, does so by the simple expedient of applying a thin paste of ordinary starch to the surface of the print. He allows this paste to dry for about 10 minutes. At the end of this period, he holds it under the tap and removes both starch and dirt by running water over the print.

SOFT DEVELOPER

FOR that contrasty subject, with very strong high-lights and deep shadows, we recently came across a developing solution that just about hits the nail on the head It is called GD-33, is easily made up from familiar chemicals sure to be found on every normally equipped chemical shelf, and is extremely stable. Made up for tray use, the

Sodium Carbonate	130 grains
Potasium Bromide	15 grains
Water to	32 ounces

ANTON F. BAUMANN

WIDELY known and admired both as a photographer and a personality, Anton F. Baumann has shot his last picture A victim to the desire for original viewpoints in photography, Baumann, a master of 35mm technique, died while attempting unusual picture angle.

an unusual picture angle.

"He had just completed a lecture and demonstration tour of a number of southern ' says the announcement of his death, "and was making pictures when he met with an accident in an attempt to obtain a 'different' angle from a high position.

"Anton F. Baumann entered the employ of the firm of Ernst Leitz as a young boy, being engaged in the research department. When the Leica was introduced he at once realized its possibilities and soon devoted all of his activities to making pictures and lecturing on Leica technique throughout the world. . . . His lectures and demonstrations were a delight to thousands of photography enthusiasts, for they taught then how simple it is to make enlargements from 1 by 11/2 inch negatives. When modern color films first appeared, Baumann immediately saw the possibilities of this new medium and devoted much of his time to it. He projected his slides to audiences throughout the country and inspired many photographers to work with this new medium."

Also, "same-size," enlarged, or reduced-size duplicates from most sizes of Professional Kodachrome Ministure sizes may be submitted, through dealer, either mounted or unmounted

HEAVY DUTY PHOTO FLOOD "HI-LO" Switch: Control switch capable of handling group of two, three, or four lamps drawing total power up to 2400 watts. For example—four No. 1 lamps, four No. 2's, two No. 4's plus two No. 1's, and so on. Unit comprises steel box four inches square by two inches high, with toggle switch lever on top and pair of outlets on each of two sides. Finished in neat crackle gray, equipped with rubber-covered, heavy-duty line cord and plug. With switch in "Hi" "Lo" two pairs of outlets are connected in series, dimming illumination, reducing current drain and heating.

TRIPLE S SUPERPAN REVERSIBLE (100-foot length, \$6; 50-foot length, \$3 25): New 16mm motion picture film Rated four times faster than Agfa 16mm Superpan Reversible, permitting two lens stops less exposure or corresponding increase in subject range. Speed combined with fine grain and brilliant gradation.

LAFAYETTE FILTERS AND MOUNTS: Available in 12 sizes to fit all lens diameters 23 to 42mm. Include light and medium yellow, light green, medium green, and red. Mounts consist of barrel and clamping ring which screws over its outer end to hold filter glass in position. Inner end of barrel slips over lens mount and has spring fingers to insure firm grip. When clamping ring is screwed into place it does not reduce inside dianieter of mount.

WESTON MASTER, Model 715 (\$24): New model featuring separate scales for low brightness range, 1/10 to 50 foot-candles, and high brightness range to 1600 footcandles. Manufacturers cite example of person sitting near average reading lamp at night reflecting five candles per square foot to indicate extreme sensitivity of low scale. On high brightness side, readings far higher than heretofore are provided with such subjects as beach or snow scenes. "High Light" scale viewing angle cut to 30 degrees for greater accuracy in measuring central point of interest, without being affected by surrounding light. Film speed range increased, providing for film speeds from .3 to 800 Weston. More // stop-shutter combinations provided on Master calculator dial. In changing film ratings, touch button and emulsion dial moves smoothly; release and dial locks securely. Hermetically sealed housing around cell keeps moisture out. Streamlined outer (see molded to fit hand, with special ribbing to prevent slipping Decorative chromium strip forms secure ribbon eyelet at end.

Speedo Print Dryer, new model (\$14.85).
Dries glossy prints plus regular matte or semi-matte papers. All-metal cabinet, with

crackle finish. Insulated Bakelite handles prevent accidentally burning fingers. Scientifically circulated and

controlled air warmed electrically. Minimum drying time, with full protection against scorching. Capacity: six 8 by 10-inch prints, five 11 by 14-inch, or more than 400 contact prints 1 by 1 1/2-inch, all in one

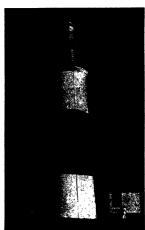

KODAK TRANSPARENCY ENLARGER (\$18.50 for complete outfit, with three filters, special masks for 35mm and "Bantam" frames, and operating instructions) For making enlarged negatives from Kodachrome transparencies or black-and-white film positives without using darkroom Accommodates either double-frame (1 by 1 1/2-inch) 35mm film transparencies or No. 828 film larger loads with either Super XX (XX616) or Panatomic X (FX616). Negatives about 2 1/8 by 3 1/8 inches obtained from 35mm film and approximately 2 1/4 by 3 5/8 inches from No. 828 frames Operation transparency, mounted or unmounted, 18 positioned in enlarger gate and hinged diffusing-glass cover closed over it No 1 Photoflood in reflector is held about five inches over gate, and enlarger shutter, opcrating only on "time," is opened for several seconds. About five seconds suffices with transparency of average density, using Super XX film. From enlarged negatives, any number of contact prints or greater enlargements may be made.

DUANCOION PF COT FILM (box of 6, 42 to 81 to 83 to 10 to 137 depending on size, 21 4/19 3 1/4 to 8 by 10 inches) IMPROVED DAYLGERT TYPE (CIT FILM (price range same as above): New PF type cut film affords greater speed methical lather. Framarily intended for methical lather. Framarily intended for both type to 15 to 10 to 1

JELL SYNCHROUED FLASH UNIT MORELY (1928-0). by means of new baseplate, synchronization is effected by mechanism of camera itself. No external synchronizing heats, devices, or connecting wires required. Battery case attached directly to special baseplate of camera by means of dovetailed alide which holds it in position. Bulb sooket of spring type. Reflector adjustable for two positions depending on bulb size. Small test lamp, located in neck of lamp socket, seat as a pilot for effecting

AS DEPENDABLE AS A LIGHTHOUSE

• More than a third of a milion enthusiatic owners have learned that they can depend on their Rolles comers for real praction work. Doy offer day, yet after year, Rolleiffex and Rollescord pictures are winning top honor in solons, contests, and the ownests. Many of the coeutry's measurement, and the contests and photographers use the Rolleiffex exclusively. But it as a comazingly easy to use that even a notice can get good results.

Sankaty Head Lighthouse, Nantucket, Mass., by Frank
A. Richardson with Automatic Rolleiflex 1/100th at 1/8.

THE construction of all Rollei cameras is so sturdy that you do not have the feeling that you have a fragile, delicate toy in your hands. You get precise focusing without having to squint through a range finder. You get pictures of a practical size in the ideal square format—twelve $214'' \times 214''$ on a roll of standard, economical No. 120 or 82 film.

And, best of all, you actually see each picture in full negative size on the ground glass focusing screen before you make it. Thus you have the opportunity to study lighting

and composition, avoiding the waste of film.

Ask your dealer to show you these five popular models:

New Standard 6 x 6 CM. RollerHex, with Zerses (7/3) Elses and 1/3.1 finder less, Compur Ropid shatter, with case 128.50 Automatic Rolleiflex, with Zeiss Tessor 1/3.5 lens and ultra fast (1/2.8) finder lens, Compur Ropid delayed-action shutter, automatic film thread, etc, complete

JACOB DESCHIN, conductor of our "Comera Angles" department, will, onsure in these columns question of general interest to anature property. If on answer is deviced by mail, enclose a stamped, addressed encelope. Queries should be specific, but MP Deschin connot understood to draw comparisons between manufactured products nor to advise on the purchase of enupment or materials.—The Edition

- Q. Is it possible to change a positive movie film to a negative? If so, how? If you have any information on how to make prints, using movie film, I would appreciate it.—J. K.
- A. A positive movie film is used to make a negative by the contact printing method. In our June, 1938, "What's New" column we announced the introduction of the Kodak John enderger, by which these small movie positives may be directly enlarged on 616 film. The resulting negatives are then used for making contact prints or, if desired, still larger pictures by the enlarging process.
- Q. I am thinking of buying another camera. How can I decide what camera and lens will suit my purpose? The pictures I take are distant access and snapshots of interesting objects seen when walking around with the camera. For years I have been interested in making color pictures and would like to know if you can give me some information on the subject. How do the Kodachrome, Dufaycolor, and Autochrome processes differ?—It was not a support the pictures and was considered to the contract of the contract
- A. Portability is probably one of the first considerations in your case. Price and size of negative are others. If you can afford it, we would suggest the purchase of a canera that will permit the interchange of cliences so that a telephoto or wide-angle cliences are that a telephoto or wide-angle cliences are that a telephoto or wide-angle cliences are the work as you describe, a lens with a speed of 1/6.5 should be ample. Adaptability for various types of work is one of the things to look out for, particularly if you plan to have but one camera. Although it is said that so single cumers is capable in a side of the control of t
- As to color photography: This has been simplified today insofar as the production of color transparencies are concerned. If you plan to do much color photography, the sizes of color film available may have some bearing on your choice of a camera. Kodachrome. Dufaycolor, and Filmoolor (Autothrome, formerly available in plates, has been superseded by Filmoolor in cut-film form but with the Autochrome emulsion) are are all similar in the sense that the color serves and the anothromatic emulsion have

- been combined, so that exposures may be made in the same manner as ordinary black lens and the panchromate remision between the same panchromate remision back of it receives the exposure through the screen. All three types are available in cut film ranging from 2 1/4 by 3 1/4 inches up to the professional stare. In addition to cut film, Kodachrome is also available in 35mm, Berspoure rolls, and in the 6 by 13cm steres sure cut film, Dulyvolor is available as a continuous contraction of the contraction of the start of th
- Q. Can you tell me the reason for the vertical line of stain running through the center of certain negatives stored in negative enclosures?— S. F. I.
- S. E. I.

 A. This is a common difficulty experienced by photographers who file negatives in enclosures having glued or parted assimptions of the center. The nature of the address of the center of
- Q. I desire information on the use of powder for flashlight photography. Would you say that its use is the answer to getting flashlight action shorts as cheaply as possible? I know that so chapt you have been as the powder so on, but outside of that would the use of powder he just as good? Please describe the technique of using powder satisfactoriy—H. B. B.
- A. Flash powder today is used almost exclusively by newspaper and commercial photographers when it is required to cover a large area, particularly outdoors at night. The low cost of flash powder as compared with that of flash bulbs is greatly offset by the disadvantages of the former. The inmediate awing to flash bulb by both ammediate awing to flash bulb by both ammediate awing to flash bulbs by both ammediate awing to flash bulbs by both ammediate awing to flash bulbs by both ammediate.

teur and professional photographers as soon as these became available is a certain indication that the higher cost of the bulbs has proved no drawback to widespread ac-

From your query we gather that you are aware of the main advantages of the bulb over the powder, so we won't dwell on them You probably also know that smallsize bulbs, proportionately lower in cost than the larger ones, will provide sufficient illumination at normal distances to give well-exposed negatives at small stops our opinion, cheapness is the only advantage that powder has to offer over the bulb, for average working conditions Mention must be made of the hazard attending the use of powder-that of untimely explosion Special care must be used both in storing and igniting powder Flash powder is fired in a device known as a flash-pan, provided with some automatic method of ignition. The powder must be exposed and not confined in a container of any sort A brief flash is obtained when powder is heaped in one spot, a longer flash when the powder is spread over the pan, thus insuring the maximum of light Instructions are supplied with each container of

Q. Since I do not own a scale with which to weigh chemicals when mixing developer, can you tell me how to measure out chemicals, using tablespoon measurement?—F. H. J.

A. We would if we could but we can't The fact is, chemicals vary in weight and so would necessitate a different table of measurements for different chemicals. While the weighing of chemicals for the compounding of photographic solutions does not always have to be critically accurate, the use of a tablespoon system of measurement would be stretching the point a little too far. By employing one of those vari-sized spoon sets used in weighing out cooking recipes, it is altogether possible to figure out a method for preparing formulas, but a weighing scale would be necessary to fix the quantities. Scales are not expensive and sometimes may be nicked un second hand for much less than their original cost. In this connection, the dollar Weigh-Spoon device mentioned in our "What's New" column some time ago should be suitable. If you employ standard developer formulas, these, as you probably know, are available ready prepared in dry form, requiring merely a stated quantity of water to make them ready for use. One manufacturer solved the problem you have manufacturer solved the problem you have in mind by providing wooden measures in each package of chemicals. These are sold under the name of "Mak-a-tube" (de-veloper), "Mak-a-fix" (fixer), and so on.

Q. What causes a partial reversal of the negative image in the course of development?—P. R.

- A. The reason may lie in fogging caused by the use of an unsafe light in the darkroom or in extreme over-exposure while in the camera. Another cause is the use of an oxidized developer.
- Q. I write music as a vocation and follow photography as a hobby. When I receive an order, for, say, 50 copies of the same piece of music, I would like to be able to make the first copy by hand and from that reproduce the

other 49 copies with the camera. Can you tell me how I can photographically copy music on both sides of the same sheet of paper?—II. K. J.

A. Aside from the method of individually sensitizing each side of the paper, you can employ a double-coated paper expressly made for the purpose you have in mind However, because there is so little demand for this kind of paper, it will be necessary for you to purchase a fairly large quantity. But since moderate quantity reproduction is required, this should offer no problem. We understand that a paper of this type, sold in large rolls, is obtainable from the Gevaert Company of America, 423 West 55th Street, New York City The company will cut the paper up into the sizes you specify We would suggest that you write to the company and state your problem, making clear your requirements, which will include the facts that the paper must be non-glossy and thin and flexible enough to permit folding without cracking

Q. What do I have to do in order to print on special cards some of the pictures which I have taken?—Mrs. C W R

A. The first step is to convert the cardinto regular photographic paper by senstizing them according to the formula given in our reply to E. W. D. in the September, 1938, issue. When that has been done the rest of the procedure will be similar to that employed in the contact printing routine.

Q. My No. 1 Auto Self-Timer exerts, in my opinion, a very great pressure, so great that I am afraid to use it lest it shall break or bend the tiny trip bar located under the cable release socket. Please advise if there is any danger of damaging the shutter in this manner. —A. K. B.

A The pressure you refer to is necessitated by the nature of the timer's design, but will do no harm to the shutter. There is no adjustment on the No. 1 timer for the pressure required to set up the delay mechanism, as there is on the No. 2 timer You can, however, feel secure in using this timer without danger of damage

Q. How can I enlarge from a wet negative?—R. L.

A. Make a glycerne "andwich" beven two pieces of clear glass. Apply a little glycerne in the center of one glass, at the west magicare on it and apply another drop on top of the negative. Place the other glass on top of the negative. When sandwiched together, the glycerine will apread, occurring the entire negative and thus preventing premature drying of the negative while being projected in the enlarger.

Q. What is a good way to copy a photograph made on a matte surface—L. D. G.

A. In order to overcome the disadvantage of the matter effect for copying purposes, and to help bring out shadow dotail, immerse the print in water, let it sook a while, and then lay it face down on a sheet, of plain glass. Squegee it down firmly until all bubbles and air pockets have disappeared. Make sure the glass is clean before you lay down the print. Face the print, through it glass "cover," towards the camera, and light it evenly by using two light sources of equal intensity, one on each side.

BURLEIGH BROOKS

Our Book Corner

THE Hook Department of Scimille American is conducted, with the co-operation of the Editors, to make a sail able to you a month the Editors select and review in these columns new books in a wide range of scientific and technical fields. In addition, they are ready at all times to advise you regarding the best avail-

able books on any subject. You are invited to use this service freely. Tell our Book Department what kind of books you want and you will be furnished with a list of audiable titles, including prices. When inquiring about books, please be specific; remember that we can be of the greatest help only when you tell us just what you are looking for.

answers to questions concerning commercial applications for new chemicals or byproducts. Although 5167 chemicals are bitself, the book is not a decionary; rather to stage and understand the processes described by patent number, potential applications, and sales possibilities. All products are tuled by common name and are in strict alphabetical order. The biastings usually include German and French names, and in the case of drugs, the Latin equivalent is also given. Nine pages of synonyms and cross references. (665 pages, 6 by 9 ninches) - 310.10 posparad—L B P

AMERICA BEGINS AGAIN

By Katherine Glover

JUST over a dwade ago Seemitis America parabol and pushed a long series of articles entitled "linele Sam Spandthrift". Those articles desired, with sharp emphasis, wasteful America methods which were depleting our forests and natural resources, that has been done in recent years to salvage what is left of natural resources, to protect our farming lands against destructive crosson and wasteful fairning practices, and to cut tumber sensufficially and reforest old interfer lands. This is a significant pointer damb. This is a significant pointer distribution of the significant proposition of the significant propositi

THE NATURE OF THE CHEMICAL BOND

By Linus Pauling

THE professor and the student will find this volume and an keeping up with the rapidly advancing theories of physical chemistry. Profolems of chemical binding are discussed, as are also the structures of atoms and molecules. The theory of the treatment is hased chiefly on the results of the quantum mechanics, with special emission of the control of the professor of the professo

GIVE YOUR HAIR A CHANCE

By John W King

M UCH common sense about hair is contained in this small book dealing with bair cure, dandriff, baldness, grey hair, and scalp diseases. It debunks hair dads, hair pomades, and false notions about dandriff. (157 pages, 5 by 7 1/4 inches.) \$2 10 postpaid. "A G L."

THE BIRTH OF THE OIL INDUSTRY
By Paul H Guldens

LEGITIMATELY dramatized, this historical survey of the early days of oil in the tastern United States makes reading that is as interesting as it is informative it begins with observations on perfording in 1627, describes the early petroleum springs and wells of the east, and carries through the uses of petroleum as a medicine as

to the drilling of the famous Drake well in 1879. Them the real fau stars. The mod rash for land, the maze of flowing wells, publicas of transportation, mixtet devel opment, taxation, battles of the off fields, to boom towns, and all the myrad of starting developments that resulted from the devel pages, 6 by 0 mices, a number of interesting photographs and maps). § 310 pest pad -APP

MAN THE WORLD OVER

By C. C. Carter and H. C. Brentnall

A DULT's who did not shine in geography in school may make up their deficiency by reading this book, though it doesn't look or read like a schoollook and sin't even bug enough to hide behind. It deals with the earth's peoples, industries, products, climates and so on, and has many maps showing special regions, industrial or chimate, but no ordinary maps. The treatment is rather high and casy, it is still, a student's book. CoR pages, 6 by 8 meches, numerous ultistrations 1 - \$3.10 postpaid 1 4 G. I.

HOUSE CONSTRUCTION DETAILS Compiled by Nelson L. Burbank

VERY little discussion and an amazing number of illustrations, photographs, working drawings, and cut-away sections fill this complete book for architects, con tractors, and builders Actual construction details, with dimensions, are given here to cover practically every conceivable detail in house construction A Shopcrafter's Corner gives plans and dimensions for many incidental pieces, such as cabinets, foot stools, shelves, benches, and the like A section is devoted to modern homes, in which there are drawings of the exteriors of a large number of types of houses (Complete index, 317 pages, 8 3/4 by 11 1/4 inches) -\$3 10 postpaid F. DICTIONARY OF SCIENTIFIC TERMS

By C. M. Beadnell, C.B., F.Z.S.

CENERAL dectonaires of the English Januage often err in defining scientific terms give only traditional definitions or else lag behind the times. This is purely a reference book containing definitions of technical terms used in the serinces, written by a scientist. (2.35 pages, 4. 1/2 by 7 inches.) \pm 3.10 postpaid $A \in I$.

HAVE YOU HAD YOUR VITAMINS!

By Harry A. Holmes, Ph.D.

THIS lattle book is written for the inledigent housewife concerned about a wise selection of food for the family, and for all others interested in vitamin therapy. In separate chapters it covers the different vitamins in connection with specific sources (60 pages, 5 by 7 1/2 inches, 3 illustrations) \$110 postpand A G I

BEYOND YONDER

Ry Oliver Justin Lee

AN unusual book, packed full of facts about astronomy, especially on the measurement of astronomical distances. One chapter tells, though not in great de tail, how a precision series for a measuring machine is made and tested (169 pages 5 by 7 1/2 inches, 14 dilustrations) - \$2.60 postpaid. A G I

PHOTOCHEMISTRY AND THE MECHA NISM OF CHEMICAL REACTIONS

By Gerhard K Rollejson and Milton Burton

It has long been known that light plays as important part in certain chemical processes. Only recently, however, have such processes only recently, however, have such processes here situefled ettenavely and photochemistry made a tool for the stately of the detailed mechanisms of reactions. The authors of this violume, while maining a critical attitude, have endeaviored to present the subject so that the read-er will not only understand it is background,

We can supply our readers with any of the books reviewed in this department. Prices quoted include domestic postage. Foreign prices are necessarily higher due to increased shipping charges.

SCIENTIFIC AMERICAN 24 West 40th Street New York, N. Y. but also realize its possibilities. Approximately one third of the book is given to presentation of the fundamental concepts required for an understanding of the effects produced by the absorption of light and the behavior of the reactive states produced in this manner. The remainder is devoted to specific reactions which can, in part, be regarded as supplementary material for the earlier chapters. Many original references are given, nine pages of appendixes, 17 pages of subject and author indexes (445 pages, 6 by 9 inches, 59 diagrams) -\$5.85 postpaid L B P

SHA SCREEN STENCIL CRAFT AS A HOBBY

By J 1 Biegeleisen

A HOBBY that anyone man, woman, or child can follow with enjoyment and even profit is offered in this clearly presented book Lamp shades, table cloths, greeting cards, invitations, program covers. and a multitude of other things can be produced in colorful designs, singly or in quantity, by the easily mastered silk screen sten oil process. The author gives all needed instructions and has amplified the text with a number of pertinent drawings and photo graphs (140 pages, 6 by 9 inches, 39 illustrations) \$2.10 postpaid A P P

AMERICANS.

By Fmil L Jordan

SERIATIM, the author gives separate historical narrative accounts of the contribution of each racial and national stock to the New World Indian, Viking, Spanish, Portuguese, French, Dutch, Brit ish, Negro, Chinese, German, Irish, Scan dinavian, Slavic, Italian, Jewish thus en abling the reader to judge which stocks have contributed the most. This is no dryas-dust history but is eminently readable. your reviewer forgot he was reading for review. The style is preponderantly narrative and occasionably a bit spicy (459 pages, 5 1/2 by 8 1/2 inches, 8 illustrations) - \$3 60 postpaid - A G I

CHEMICAL PIONEERS

Ry Williams Haynes

N the details of their accomplishments, the story of these 15 builders of progress is of great interest to us today; their constructions have become our great chemical industries (288 pages, 5 1/2 by 8 inches, 58 illustrations, index.) - \$2.60 postpaid I. R P

MAN AND HIS LIFE-BELTS

By E. T. Bell

"YNICS will enjoy this book Beil is a A noted science teacher who has written other cynical but penetrative books, using a sharp pen. He is aggravating, irreverent, iconoclastic, skeptical, enjoyable (unless the reader were a conformist, in which case the effect would be most irritating) and always witty. The "life-belts" are government, scientific invention, economic science and religion (of which he disposes). He says: "The happiest people today are those who know nothing." This sounds true. anyway! (340 pages, 5 3/4 by 8 1/2 inches)

TELESCOPTICS

A Monthly Department for the Amateur Telescope Maker

Conducted by ALBERT G. INGALLS

S of ar as your scribe recalls, the 30" reflecting telescope described below is the largest yet made by any amateur since this journal revived the art of amateur telescope making 13 years ago J. H. Hindle, of Witton, Blackburn, Lancashre, England, built it and, when invited to describe it, wrote the following

"THE mirror is a Chance disk, 3 1/2"
thick, with a focal length if 120".
The aperture is 30" (f/4). It is floated on a system of triangular supports, contacting the underside of the mirror at 18 points.

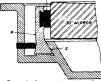

Figure 1: Cross-section of the cell

l Hindle's well-known system, described in the book 'Amateur Telescope Making,' page 229.—Ed l. A cross-section of the mirror cell, with reference to the edge support, is shown in Figure 1. The annular ring, R, is divided into 12 segments, each of which has vulcanized fiber inserts, I, which come against the mirror. Two whole fiber rings are turned, dovetail shape, then sawn into 12 sections, and forced circumferentially into position. Each segment of ring. R, is forced by means of two screws to its final position against the inclined surface, S, and in this position the fiber inserts are bored out a few thousandths larger than the mirror itself. In this way an adequate edge support is provided, and it is impossible to pinch the mirror by tightening the screws. When these are released, however, and the segments backed off or lifted out there is ample clearance for the extraction of the mirror.

"The tube is constructed from solid-drawn steel conduit, such as is used for electrical

Figure 2: The tube construction

wiring purposes, and the lengths are threaded through circular rings of heattreated, high tensile aluminum alloy. These rings are securely clamped to each tube by means of a taper fitting such as is used for attaching ball bearings to a straight shaft (Figure 2). The diagonal bracing is of high tensile steel wire, which is pulled taut by means of screws at the bottom end of each tube, near the mirror mount. A perfectly rigid tube of minimum weight is thus obtained

"The four arms of the spider carrying the diagonal are of phosphor bronze sheet, mounted on the extreme end ring, with provision for concentric adjustment.

"The diagonal mirror is 7" minor axis, and about 1 1/2" thick, mounted in an alumnum and brass cell which has a tubular stem, so that electrical means of slightly raising the temperature of the back ade of the plane, to avoid dewing, can be adopted, as described in 'ATMA' by Dr. Steavenson.

The primary mirror is not perforated. It is collimated with reference to the brass sleeve which forms the center of the spider, critaring its reflection precisely concentre with a ground spot, exactly in the center of the mirror itself. The eyepice support can be readily detached from the tube in necessary, and there is a considerable range of adjustment longuidinally. Being the contraction of the contraction

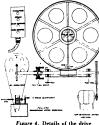

"The polar axis is built from a 5" steel tube, with 1" thick walls, and the ends plugged solid. It is supported in ball bearings, one immediately below the fork, and the other immediately below the worm wheel. The general design of the mount

Figure 3: The nearly completed telescope erected in Hindle's plant (Union Engineering Works)

for a latitude of 51 1/2° is clearly seen from Figure 3, the fork itself being a substantial iron casting of 'U' section, split where it alips on the top of the polar axis, to which it is firmly attached by compresson bolts. A segment of a worm wheel on the trunmon of the tube enables the telescope to be adjusted in declination, through the medium of a worm and spur gear, with a flexible joint to a broom handle

within reach of the observer. When the

inclined steel handle and its nut are released, the tube can be moved to any ap proximate position by hand

"The drive to the polar axis is possibly to some extent novel. The worm wheel on the polar axis is definitely fixed to it, the usual clutch being dispensed with. That enables the wheel steelf to be more precisely mounted, and the engagement of the worm and wheel more definitely adjusted The primary drive is by gramophone motor, through a 60-to-1 worm gear, which, in turn, through a friction drive, rotates the main worm shaft and the wheel on the polar axis, the latter reduction being 360to-1 (Figure 4). Particular attention is directed to the small worm gear, which is carefully assembled and runs in ball journals to reduce friction to a minimum, so that the gramophone motor is not overloaded. The pitch of worm and wheel is 10 D.P., that is π/10, and the pitch-circle diameter of the worm is 0.75", so that the angle of the thread is 7 1/2°, which practically gives irreversibility. The compression springs on the friction drive enable the necessary power, with an ample margin, to be transmitted to the main worm shaft.

"The gramophone motor is to be independently mounted so that no vibration or electrical hum can be transmitted to the telescope. At a speed of about 60 r.p.m. the normal speed of the polar axis is se-cured, and this is capable of permanent and delicate adjustment. Energizing a small A.C. electro-magnet entirely releases the brake on the governor of the motor, and allows it to run at top speed. This occurs when the accelerating button is depressed, to overtake an object in the field of view. The retard button simply interrupts the gramophone motor circuit, allowing the object to overtake the telescope.

"Rapid adjustment in right ascension is effected by means of a separate 1/4 h.p. motor, which runs in either direction as desired. Due to the greater power of this motor, the friction drive loses control, and

THE BEGINNER'S CORNER

TRIPODS instead of fixed pedestals are destrable in many instances for first telescopes, because first telescopes usually are small enough to be portable. Light, flumy tripods, however, are too shaky for a telescope, because the telescope magnifes.

the shakes in the same measure as it mag infines the object looked at. Hence a really solid, he-man tripod should be built, in stead of the too common "pansy frait". Give it good husky legs. Usually, however, you will want it portable, but its length will defeat this unless you make it jointed—and then comes the question of a joint that won't, in turn, defeat the effort to make it rigid.

One kind of folding legs is shown in the accompanying photographs of a triped made by F. M. Garland, 1006 Davis Ave., Pittaburgh, Pa. These fold outward and upward.

rather than inward, and thus nest clover when folded. The tripod has three hinged central braces in addition, made of strap metal slotted for adjustment and provided with a wingout for tightening. These braces are far enough above the knee joints of the legs so that they will not extend be low the latter when the tripod is folded.

Main feature of Garland's tripod is the knee-joint which, once locked, is as sold as a himan knee in a plaster cas! On the outer not the inner-side of each leg is a heavy backflap linge, as shown in the left hand closeup, and on the inner sides are metal-strap provided at their tops on a serwe and side shotted near their bottoms. Each slot has a bolt and wingnut for tightening

Other stiffening and strengthening details show in the photographs. The tripod shown weighs about 15 pounds and is very rigid. The refractor seen on it is an old 3 1/2". Breshoer

TELESCOPTICS

(Continued from preceding page)

the polar axis make a complete revolution in about a minur. Owing to the limitation of power that can be transmitted to the friction dreve, and the practical irreversibility of the small worm grar, the gramophone motor is quite unaffected by the rapid adjustment taking place, and continues to run on as usual limitedately, therefore, after the 1/4 bp motor is disconnected, the furtions dreve instantly is of time above. The results of the properties of the properties of the properties of the prosent of the properties of the

This ends Hindle's description. Readers of "ATM" and "ATMA" will be compared to "ATM" and "ATMA" will be compared to the compa

edition, of 1935), this is the same mirror Hindle enjoys making telescopes Hav-ing made them, he gives them away! However, lest about 10,000 readers obey that impulse to rush applications for free 30" reflectors by cable, we hasten to add that he hasn't exactly given away his two large telescopes, a previous 20 1/2" and this 30", in quite that way. He has, however, commendably arranged to place them where they will work hard for astronomy. The 20 1/2" (see its photo in "ATM," page 153) has been in the hands of Dr. W. H. Steavenson, a prominent English variable star observer, more widely known by hundreds of astronomical friends in Britain and America as "Steave," who contributed the chapter on dewing of optical surfaces, in "ATMA" The new 30" is being mounted in the grounds at Cambridge University Observatory by arrangement with Sir Arthur Eddington, where it will be available for the use of the Professor's staff Later Dr. Steavenson hopes to be in a position to make regular use of the newer instrument himself

ANT month in this department there was a long article by Hendrix and Christie, of the Mt. Wilson Observatory, on the Schmidt ramera, and now we have the following comments on that article written by Prof. C.H. Smiley, Director of the Ladd Observatory at Brown University and a leading exponent of the Schmidt camera:

"It is with some hesitancy and considerable distaste for the task that this criticism of the article by Hendrix and Christie in last month's Scientific American is written. I am deeply indebted to Mr. A. H.

Joy of the Mt. Wilson Observatory and to a lesser extent to Mr. Hendrix for valuable assistance and advice in 1937 in connection with improvements made on the Ladd Observatory Schmidt camera which had just been completed. I am well aware that Mr Hendrix has made more Schmidt cameras than any one else on earth. If I were asked where the outstanding authorities in astro nomical optical work were located, Mt Wilson Observatory and Hendrix and Christie would come first to my mind

"Even so, one of the sentences early in the article by Hendrix and Christie seems to me to be distinctly unfair "Several articles have been written about the Schmidt camera since the inventor set forth its principles in 1931, but little that is new has been included in these discussions. It is true that Schmidt was a genius and that he did state most of the important facts in his original article. However he did not give a mathematical design for the correcting plate, he did not give any method of testing nor was his method of making a correcting plate revealed to the public until after his death These important deficien cies have been taken care of by papers by F B Wright, B Stromgren, H A Lower, Y Vaisala, A DeVany, and others

"One might overlook a single ungenerous remark in the early part of the article but a considerable amount of material presented in the latter part of the article has previously been published by others, yet the article does not indicate this. A recent letter from Christic suggests that Hendrix and he knew all these things before others published them I do not question the ver acity of this statement. However, priority in scientific matters is usually established by publication in a journal generally avail able to others. On this basis, F. B. Wright and B Stromgren should receive credit for their publication of the mathematical design of the correcting plate, and other acknowledgments of priority in publication should have been made

In brief, I feel that the ungenerous and misleading statement concerning carlicipublications and the failure to mention the people who have made information on the Schmidt available generally are unfortunate, particularly so in view of the fact that Hen drix and Christie have had most of the in formation presented in this article for the past five years and have withheld it from publication during that interval

RULE for finding sagitta of a mirror, expressed directly in sixteenths of an inch, offered by Joseph Dwight, Hyannis, Mass Divide aperture by focal ratio.

To measure depth of sagitta on a mirror while roughing out, Lloyd Anderson, 11909 Vicente Blvd., West Los Angeles, Calif., puts a small drop of soft putch at the center and places a steel straight-edge across the nurror, pressing the pitch down Then, with a calipers, he simply measures the thickness of the pitch. Automatic feeler

OREIGN telescoptics is one of the hobbies of R. L. Beardsley, 2515 W. 21 St., Los Augeles, Calif., who reads about 769 foreign languages He says G. O Bjordal, Box 111. Askim, Ostfold, Norway, is one of five TNs in that town who would like to receive photographs of American TN's telescopes. They read English.

TRADE MARKS AND UNFAIR COMPETITION

By ORSON D. MUNN

A TRADE MARK is an intangible asset of a business, yet its actual value may grow so large that it becomes the very foundation on which depends the whole structure of the business. Because of this fart, every business man should have available such information on trade marks as will enable him to judge with a fair degree of accuracy the desirability of any mark which he may be considering.

Here, in one handy volume, written in non-legal terms, is a simple yet comprehensive interpretation of the Federal statutes and the body of common law relating to trade marks and unfair competition

CURRENT BULLFUN BRILFS

(The Editor will appreciate it if you will mention Scientific American when writing for any of the publications listed below.)

TELEVENION CYCLOPERIA, compiled by M. N. Bertman, a profesterate booklet which will bring the reader completely up-to-date in the senson nonenclature and practice. Thoroughly illustrated with drawings and photographs, it covers the entire field from "Abertation" to "Work Function" an appendix pust soft the fundamental principles of television as a running story, increasingly told Scientific American Book Department, 24 West 40th Street, New York. City. "50 cents."

New Houszons or Insustrat Timouer Ri-MARCH is a 62-page booklet that presents
"a tour through the present into the future"
it covers scentific research and its applications in industry throughout a broad field
ranging from automobiles and chemicals
through health and homes to rosds, rubber,
vason, and wood. It is essentially a highinghired survey of what will be accomplished
in the future, however, the proposed proposed to the
lations, General Motor Corporation, 1775

Complex States

**Complex Stat

METALIZING HANDBOOK is a 26-page booklet which gives complete details on metal spraying, together with a series of pictures which shows specific applications. The equipment necessary for such work is listed. Metallizing Company of America Inc., 562 West Washington Boulevard, Chicago, Illinois - Craiss.

TYPICAL NICKEL ALIOY STALES AND CAST LOONS EMPLOYED IN DIESEL CONSTRUCTION IS a single sheet tabulation which covers these metals as used in light, medium, and heavy Diesel engines. It tabulates engine parts, recommended compositions, mechanical properties, and heat treatment. The International Nickel Company, of Wall Street, New York City—Gratis.

THE INDUSTRIAL USES OF PRISTO SOUND RECORDING EQUIPMINT is a 12-page pamphlet, illustrated with a number of photographs, which describes this type of high-grade recording equipment and sets forth a number of the uses to which it can be put. Presto Recording Corporation, 139 West 19th Street, New York City—Gratis.

SEALAIR WINDOWS is a 10-page, completely illustrated booklet which shows and describes all-aluminum windows in stock and standard sizes. It should be of particular interest to the home owner who is considering building or rebuilding. The Kauneer Company, Niles, Michigan.—Gratis

Practical Television by RCA is a 40-page book which is particularly concerned with circuit design, anienna installation, and reception. It is published for service men, dealers, schools, and anyone interested in a survey of television as it stands today. It presents a general discussion, technical description of receiving circuits, details of television receivers, a section devoted to general service problems, and a group of television definitions. Obtainable from RCA distributors or direct from RCA Manufacturing Company, Camden, New Jerser.—25 cents.

New Photocaraty Record is a stemgraphic report of the second annual short course in news photography at Kent State University. It covers, in lecture form, practically the entire field of photography, from the latest developments in cameras and equipment to color photography, phophotography, and so not A Clarance Smith, Associate Professor of Journalism, Kent State University, Kent, Ohio.—425.8

DYES is a 12-page illustrated booklet which has been prepared to correct certain mis-conceptions. It clarifies, for example, the stution as regards the dependability of American dyeatuffs and the identification of color-fast mechanistes. It also tells of the research which is being carried on to modury will retain its present high standards. E. I die Pont de Nemours & Company, Inc., F. illumpton, Delawore—Corais.

ALILI'S RADO BULBER's HANDROOK IS 3D page, throughly illustrated booklet which gives the resider some theoretical background, together with a knowledge of radio circuits. A short section is also deviced to amsteur radio—bave to operate an annateur radio station and how to send and receive in code. A group of circuit diagrams gives the reader something concrete to work on Allied Radio Corporation, 833 Fest Jackson Boulevard, Chicago, Illinois.

AN ADDRESS BY EDWARD G. BUDD is a short, compact reprint which gives a brief but thorough survey of railroad travel in the United States as it is today. It gives a better overall idea of how the railroad putter has changed within the last few years than could be obtained from many a long-winded technical discussion. Edward G. Budd Monufacturing Company, Philadel-phia, Penaryleum.—10 cents.

PHILIPPIN: MININC YEAR BOOK contains a complete history of the various maining dustricts in the Islands, the history of the leading producers, and a review of the base meast undustry. The book is profusely illustrated and the contained second complete assistics and directions of second complete assistics and directions of the profusely distributed and results obtained. Rolph Keeler, Post Office Ros 769, Manula, Philippine Islands.—41.00.

This American Way in Industrial Research is an 8-page illustrated reprint which describes specifically the work of Mellon Institute and other institutions which are today shaping our industrial future by the work which they are doing in various fields of research. Mellon Institute of Industrial Research, Pittsburgh, Pepnsylvania.—Cratis.

BATTLE OF BATHS

WO bath preparations similar to bath Two bath preparations similar to salts, both bearing French names, were involved in a recent suit for unfair competition and trade-mark infringement. The manusscturer of a bath preparation bearing the trade mark "Bain de Champagne" brought suit against a competitor selling a bath preparation under the name "Bain Mousseux, charging that the names were confusingly similar to each other It was pointed out that the word "Bain" meant bath and that accordingly the plaintiff's trade mark meant bath of champagne whereas the defendant's trade mark meant sparkling bath. The defendant's preparation when added to the water in a bath conveyed a sparkling or effer-vescent character thereto. The plaintiff con-tended that the word "sparkling" used in the defendant's name would immediately suggest champagne and for that reason the defendant's name would necessarily be confused with plaintiff's.

The court, however, pointed out that in sound and appearance the two names were quite different and that furthermore the word sparking suggested many other products beades champagne. Since the defendant's name was merely descriptive of one of the characteristics of the preparation the court refused to restrain the use thereof.

CHORNE

THIOSE of us who have difficulty in tremembering more than the chorus of a song and find ourselves humaning or singing assong and find ourselves humaning or singing asthe chorus of a song over and over again will receive a certain amount of moral sustleanance from the judicial declaration that the chorus forms a substantial portion of a song, in a recent sust for copyright infringament the owner of the copyrights on two songs charged that a printing company was guilty of copyright infringament because it had sold printed copies of the choruses.

One of the defenses raised was that the mere copying of the choruses did not constitute an infringement of the copyrights because the choruses did not constitute substantial and material parts of the songs. The Court held that this defense was without merit, stating.

"The chorus of a musical composition may constitute a material and substantial part of the work and it is frequently the very part that makes it popular and valuable."

TURN AROUND

IN a recent decision of a Federal Court
the trade mark Run-R-Stop was held to
be infringed by the trade mark Stop-A-Run.
In the suit in question the manufacturer of

a fluid to be used in stopping runs in this stockings charged a competition, making a similar product, with unfair competition and trade-mark infringement. The Court found that the plaintiff had used its trade mark Run-R-Stop for many years, had spent a great doal of money in advertising, and additionally assume that the product was manufactured by the plaintiff.

The Court recognized the differences between the two names but came to the conclusion that, due to the cuphonous similarity between them and due to the further fact that the packaging and dressing of the two products were very similar, the use of the name Stop-ARun by defendant was likely to lead to confusion and constituted trade-mark infingement

ADDENDUM AND

DEDENDUM

THE Court of Gustoms and Patent Apppeals has allowed a patent on toothed gearing in which the teeth of the driving pinon are all-addendum and the teeth of the driven wheel are all-dedendum and with a pressure angle lying between 22% degrees and 30 degrees. The terms addendum and derlendum as applied to gearing means that the teeth are outside and made respectively concess passing through the putch point of the grars and which are coaxial with the axes thereof.

The Patent Office had refused to allow the patent on the grounds that the provision of pinnoss in which the teeth were all-addendum or all-defendum was old and that the pressure angle of the teeth was more or less optional. On appeal the Court of Castoms and Patent Appeals reversed the Patent Office and held that the present patent of the patent of the patent patent and produced new results which were not attainable prior to the inventor.

In reaching its decision the Court was influenced by the affidavits of several experts who told of the many years of experimentation required to develop the gearing and also stated that the particular angles referred to were critical.

JEWELLED SHROUD

THE utility of a design has no bearing upon the validity of a design patent This principle of patent law is illustrated by a recent suit for infringement of a design patent for an automobile exhaust abroad

Briefly stated, the design patent related

to an exhaust shroud having a sloping too surface in which a glass reflector pred vas mounted so that the headlights of a car approaching from the rear would be reflected by the sewel After considering the elements of the design or appearance of the shroud and finding that they were of more cless conventional character the court briefly considered the utility or function of court pointed to the state of the court pointed for the state of the court pointed for the state of the court pointed for the state of the parent, stating upon the validity of the patent, stating the state of the patent stating t

"Moreover, we must keep in mind that the utility of the combination of the glass jewel and the exhaust shroud is not involved. Utility plays no part in determining the validity of a design patent."

PROFESSIONAL

MISREPRESENTATION

A RATHER novel defense was raised in a recent proceedings brought by the Federal Trade Commission against a manufacturer of a sopa and outnemn used in the treatment of skin diseases. The Federal Trade Commission charged that the manufacturer was guilty of unfair methods of competition because of materpresentations appearing in certains of the advertisements appearing in certain of the advertisements under the competition because of material states of the safetiments of the safetiments.

One of the defenses nased by the manufacturer was that he adventuements in question appeared in a professional journal and that the physicians who read the journal would not be misled due to their medical knowledge A Federal Circuit Court of Appeals rejected this defense on the grounds that if the adventuements were false and misleading it was immaterial whether or to the court of the cou

The Court also stated:

"Conceding the somewhat violent assumption that prospective patients never read medical and nursing journals, we do not concede either the ethics or the law of a proposition which puts a premium on a failure in wickedness."

R O

RATHER intimate and personal issue were considered by the Patent Office tribunals in a recent opposition by a promient soop manifecturer against the application for the registration of the trade mark. "Noho" by a doodorant manufacturer. The Court of Customs and Patent Appeals found that the soap manifectured had popularized the letters "B.O." by extensive advertising and had identified them with the words of the control of

The Court found that the soap manufacturer would be damaged by the registration of the trade mark "Nobio" and refused to permit the registration, stating:

"Il is evident, we think, that, although the terms 'Nobio' and 'B. O.' do not look exactiv alike, the term 'Nobio' all be pronounced as though it were spelled 'No.B-O.' that appellee intended that its term 'Nobio' should be understood as meaning 'no B. O.' (no body odor), and that it will be so understood by the purchasing public."

Industry Accepts

....THE ONLY National Publication to show a consistent FIVE-YEAR GAIN in Advertising Lingge, 20% GAIN IN 1939 OVER 1938!

Dependence follows quickly upon acceptance and Scientific American, because of its exhaustive treatment of industrial research, has won the acceptance of leaders of American industry.

Not content with merely reporting the news of the frontiers of research and invention, Scientific American long ago began showing industrial leaders how to apply the new developments from those frontiers to today's procedure.

And in today's procedure, Scientific American plays a definite part. Industry depends upon this publication to bring it the guiding facts that lead to the purchase of the products advertised in Scientific American pages.

Build your sales upon this dependence. Know that your selling facts are read by the men who do the buying, in the publication that impels their buying interest.

Ask us to show you copies of the letters received from American industrial leaders seeking buying guidance from Scientific American.

50 Years Ago in . . .

(Condensed From Issues of October, 1889)

MAINE—"The steel cruser Maine, in course of construction at the Brooklyn Navy Yard, is now in skeleton condition, most of the frames being up. When completed she will be the largest vessel ever built for the United States Navy, being of 6648 tons displacement. The mammoth shed where the work is in progress was erected

during the Civil War Doubtless, to its constructors, the dimensions of this shed seemed sufficient for the longest craft that was likely to be built. Yet the prow of the Maine, with its stell ram and spur, extends many yards into the open. Inside this shed nearly three hundred men are now at

Y.

BENDING - "The largest bending rolls that the Niles

Tool Works are now building for the Mare Island Navy Yard, San Francisco, possess very interesting features. This machine will bend mild steel plates 2 in. thick by 22 ft wide. It is guaranteed to bend armor plate 1½ in. thick by 22 ft wide. The work is done by four forged rollers, two in the center, arranged one vertically over the other, to grap the abeet between them, and one on either side of the center to bend the sheet."

FLOOD.—"During the Conemaugh flood, thirty-two locomotives, some of them weighing 91,640 lbs., were tossed about like corks, 23 of them being conveyed an average distance of 1347 feet down stream, one song 4844 feet, the shortest trip being 480 feet."

PARCELS POST—"In June last the Postmaster-General submitted to the Chiliar minister the draught of a convention between the republic of Chile and the United States for the establishment of a percels post system and a postal money order system between the two nations."

TRANSANDINE RAILWAY.—"The Andes are being crossed at the Uspallata or Cumber Pass, where there will be a tunnel S.I mules in length, at an elevation of 10,450 ft. above sea level. The pass itself is nearly 3000 feet higher, or at 13,015 ft. and is situated 4½ miles south of Anonagua and 334 miles north of Tupungato, in 33 degrees S latitude. It will thus be seen that the summit level of the Transandine Railway is far above any European lines, which at the Rigi reach to 5753 ft., and at the St. Cothard 3786 ft."

WAGES.—"Some paper has started the silly question, 'Do Inventions Decrease Wages?' Certainly they do not. On the contrary, inventions increase wages, shorten the work day, and decrease prices. In fact, inventions constitute the only possible way by which labor can be emancipated from drudgery, long hours, and poor pay. Inventions are increasing every year, and wages are constantly advancing in all countries where they are utilized."

YELLOW FEVER—"Dr. George M. Sternberg, surgeon in the United States Army, has just returned from a six month; say in Cuba, where he has been continuing his researches with reference to yellow fever. He has brought with him specimens of microbes, with which he will continue his investigations during the winter at the Johns Hopkins University.

PHONGGRAPH—"In reply to numerous inquiries we can only asy the phonograph has not yet been reduced to that simplicity and perfection of operation necessary for its general sale and introduction. It is true, several examples have been produced which are in use, and many interesting experiments have been made.

But in most cases, in order to get really assistatory recalls, we believe it needs the employment of an expert to watch, adjust, and work the instruments We are informed the machine has recently been improved to as to dispense with all adjusting the state of the state of the state of the matter, and machine it is not to the hands of everyone. If the phonous the reached this stage of simplicity and perfection, we predict for it a bright future."

WHEELS—"Carriage manufacturers are predicting that in the not distant future wooden wheels will be done away with.

wooden wheels will be done away with, and steel wheels substituted, on account of the increasing scarcity of lumber for wheels."

CRUISER SPEED.—"Advices from San Francisco state that the calculations regarding the horse power speed developed by the crusser Charleston, just completed by the trail board, show a maximum horse power of 7093 and an average horse power of 6816 for four hours, average speed, 18.75 knots, though a maximum of 19½ knots was developed for a short time."

DANGER.—'The most curious protest against railways ... was that drawn up by the Royal College of Bawaran Doctors, recently discovered in the archives of the Nurnberg Railways at Furth, the first German line constructed. It contains the following passage, ponting out the danger of the new system of travel: Travel nearrings drawn by a locomotive ought to be forbidden in the interest of public health. The rapid movement cannot fail to produce among the passengers the mental affection known as

DRILL—"An interesting electrical machine can be seen in operation on the framework of the new warship Maine, in the Brooklyn Navy Yard. It is a drill instead of the slow and tellous pawl and ratchet hand drill commonly used, is one that is set a-whirling by an electrical current sent through carefully insulated wires. A three-quarter inch hole in a three-quarter inch plate can be drilled in less than a minute."

OUR POINT OF VIEW

Co-operation

HOPE for a future of asfer motoring, and for longer lives for members of the motoring public, may be gleaned from three articles in the present number. First is "Insanity at the Wheel." on page 199, econd is "Self-Contained Unit Headlight," and third is "Motoring Eye Health for 1940," the last two appearing in the Digest section. It does not take much reading between the lines to realize that here are examples of tangible cooperation between diversified forces, all acting toward the common good.

With psychiatry bending commendable efforts toward weeding out the unfit among drivers (we hope this will continue on an ever-expanding scale), the electrical industry dreeting research toward better and safer lighting for motor cars, and the glass companier developing better and safer safety glass for windshields and car window, we find many reasons to believe that the death toll on the highways, reduced in 1938, will be still further reduced during 1939 and 1940.

Now, if more and more drivers will only awaken to a realization of what is being done to protect them sagnant themselves and will contribute their share to the co-operative effort, we can really get somewhere in the matter of highway safety. Naive though it may seem at first blush, it is nevertheless a fundamental truth of motoring that individual applications of the Golden Rule to the rules of the road will go a long way toward making for safer and happier driving -A. P. P.

Pan-American Trade

TRADE with Mexico and community South America looms large in the thoughts of some of this country's commercial interests. Partly, there is the profit motive but more important is the item of self defense. Freer intercourse between the peoples of the Americas. more enlightened good-will and mutual respect, and an equable exchange of goods and services, all will assist in stemming the tide of foreign ideologies which threaten the peace and independence of several of our southern neighbors. The less this hemisphere is dependent upon nations of other parts of the world, the less likely there is to be coercion-economic, political, and socialfrom those quarters.

Yet despite the need for closer cooperation so that our export-import

T. Hart Anderson

RICHNESS of achievement marked the life of T. Het Anderson, nationally known pattern lawyer and director of Scientific American, who passed away at his New York City home on August 15. His age was 74. An active of Louisville, Kentacky, he had been an Examiner in the lawyer in Boaton and New York for 44 years, and our director for several years.

"Judge" Anderson's genial smile will long live in he memories of his friends and associates. Many will, indeed, continue to try to emulate him, for he had attained that precious friendly calmines, so rare in these rushing times, that remains unrufilled by the affairs of little men. Posessed of a judge-like dignity, and a superior knowledge of law—especially of that pertaining to pieter he commanded the records allow.

His gentle manner, coupled with his many successes in significant litigation, suggest as an epitaph for him the old Latin phrase of lawyers "Suaviter in modo, fortiter in re."

problems might be solved, there are those who blandly refuse to open the hatred mids to logic. Notorois is the hatred some South Americans have for the linited States. This attitude, however, is understandable—and curable, too, if it is properly attacked, vigorously and with open minds and sympathetic hearts. But those who despise all Norte Americanos fall far short of being as stuppd as some in this country who wish to mercase their export business. These are the ones who, with important export products, never, or half-heartedly, attempt to get the prospective buver's vigorous.

Many American companies think that they can get foreign business by the same tactice with which they get it at loom. They believe the star safesman in the States can get volumes of business abroad whether he knows the language, habits and customs, likes and dislikes, and manner of doing business of the foreign people to whom he would sell. These same companies answer their foreign correspondence incompletely and apathetically. Cases are known in which queries, involving the expenditure of

large sums, when sent to European producers and to this country simultaneously, elicited detailed answers by air mail from the former, with technical data and catalogs, and a mere acknowledgment by ordinary mail from the American companies concerned.

The answer is obvious. If we are to rexpand our expand our expand trade—if we really want to!—and thus keep our farms and factories operating at a higher efficiency, we must develop a new understanding of the problem. It becomes necessary that are the problem. It becomes necessary that are the faults in our system and then use a little gray worth it—for all the Americas.—F.D. M. worth it—for all the Americas.—F.D. M. and the stakes are sufficient to correct them.

Degrees, Comfort

E VERYBODY knows that there are On a given day in midsummer, let us say. it stands at 88 degrees, which is really hot in some places, yet the day may be quite agreeable. Perhans on the next day the mercury has fallen a full ten degrees. yet life may be almost unbearable. We say that the first day was dry, while the second was muggy. In more scientific terminology, the relative humidity-that is, the ratio of the amount of water vapor mixed with a given amount of air to the amount that the same air will hold at the same temperature—has changed from low to high. Moving up more closely to what actually goes on when the muggy day comes, the number of water vapor molecules in the air has increased, the effect is to cause a larger number of speeding molecules to leave the air adsecent to the victim and add themselves to the sticky film of liquid in which he is bathed, in proportion to those which, similarly speeding, simultaneously escape from him. Thus his net evaporation is reduced and he probably goes around all day "beefing" about it's being hot and getting himself glared at by others who already know it. Yet on such a day it isn't as hot as it was yesterday when it was so comfortable.

A thermometer gives but one factor in measuring bodily comfort; relative humidity adds a second, while a third is air movement.

An instrument combining these three factors is now available but before its use can become widespread the public must be taught what relative humidity is. By publishing relative humidity percentages some newspapers arouse curriculty and in time the scientific point of view may be inculcated. Good work—keep it up—A. G. I.

Personalities in Science

ONE generally thinks of an engineer of as a technical man talking in mathematical terms and thinking with a slide rule. But O. B. Hanson, vice-president and chief engineer of the National Broadcasting Company, is one of the Tare executions.

"OB." as Hanson is known to his associates, is essentially an artist with the inquisitive mind of a scientist. Thinking in terms of an artist and working as a scientist is the secret of Hanson's achievements in the field of radio and television.

Born at Huddersfeld, England, Hans nw sab rought to the country at the age of one, when his father moved the family woolen business to Connecticut. Young Hanson showing an early aptitude for music and drawing, his family later sent him back to England for eight years of study at the Royal Masone Institute in Hertfordshire where, in addition to his regular classes, he had special instruction on the volum.

Hanson says that he never really acred for the volin and wanted to play the piano. but his family insisted. However, he had no intention of making music his life work. He would probably have become an architect, if it hadrit been for the audden death of his father. That event put an end to his father. That event put an end to his father. That event put an end to his lather. That event put an end to his father. That event put an end to his father. That event put an end to his father. Underwood Typewriter Company's factory at Hartford, Connecticut.

Hanson's interests became centered on wireless telegraphy in 1912 when the Titanic rammed an iceberg in the North Atlantic and sank with an appalling loss of life; for it was only through the ship's wireless that a horrified world learned of the tragedy. It was not wireless telegraphy as such, however, that intrigued the eager youngster; it was the unexplored possibilities of its development. He soon began to think in terms of radio telephony and, later, of television. Here was work to tax the artist's imagination and bring into play all the skill of the scientist. Here was his life's job, an

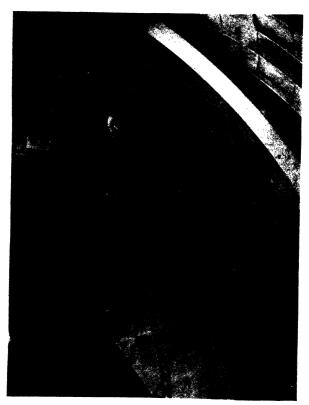

O. B. HANSON

unexplored field in which he could revel in 1917. Hanson became a member of the Marconi Company's engineering staff, rising to the position of chief testing engineer in six months. The war over, he had a short ling as head of his own electrical business in Hartford Then in 1920, station KDKA, Pittshugh, owned by the Westinghouse Company, had begun regular broadcasting and Hanson built himself a receiver and listened to the first test transmissions. Immediately his course was decided. That course led eventually to his present position.

However, as in all good stories, young Hanson started at the bottom of the radio ladder. His first job was with station WAAM. Newark. New Jersey, where he held the varous positions of chief engineer, operating engineer, program director, and announcer. For all practical purposes, Hanson was station WAAM. In the years that have followed, the world has seen the rapid tree of radio san nat and as an industry. Hanson's own rise has been always a step ahead.

It is not an exaggeration to say that Hanson lives, eats, and sleeps his work. His home at Westport, Connecticut, is a veritable testing ground for technical improvements in both radio and television He designed it himself and it contains many special features that only an artistic man of science could possibly have continued. Even his hobbiesphotography, yachting, and music-become factors in his regular work; photography he finds has given him many useful ideas in the development of television; on his yacht he has been able to carry out much experimental work in marine radio telephone; music is almost a fundamental of radio programs.

Hanson is a bachelor. His present family consists of a registered black and white Springer spaniel with a litter of eight pups. He is a fellow in the Acoustical Society of America, and a little member of the Veteran Wireless Operators Association Incorporated,

WHERE, OH WHERE HAS MY LITTLE TRUCK GONE?

Insanity At The Wheel

SWAGGERING mto the Detroit licome bureau, T-102 was blissfully unaware of the blow that fate was about to deal bim. He had lost his tax driving permit and driver's license some weeks earlier, and now demanded permission to resume earning his livelihood by piloting a cab through the streets of the nation's fourth city.

"See Judge Maher," said the man at the counter, and T-102 swaggered out, confident that the judge would restore him to his seat behind the wheel.

Into the austere courtroom of Traffic Judge Thomas F. Maher walked T-102 next morning, and hardly had his law-yer presented a petition for recovery of lost privileges than the judge passed him along: "Have a talk with the traffic psychotechnologist."

T-102 blinked at this command, comprehending not at all, and shortly thereafter stepped briskly from the elevator into the 17th floor hallway of nearby Barlum Tower, opened a door marked "Psychopathic Clinic." and handed across the counter the brief court order requesting his examination.

It was here the 36-year-old taxi driver became T-102, a psychological guinea pig in whom Alan Canty, the psychotechnologist whose official designation had so startled this visitor, took an interest no greater nor less than in any of the many traffic violators who expose their mentalities to his searching inquiry overy week.

Canty put T-102 through the ropes, over the jumps, across the hurdles.

To What Extent do Psychopathic Cases Contribute to Motor-Vehicle Accidents?...Weeding Out the Unfit by Specialized Analysis of Attitudes

By ANDREW R. BOONE

Y OU smash into the car ahead, dash past the red signal, send pedastrians serving for safely as you saying the serving serving serving the safely as you saying the serving the safely saying the safely saying the safely saying the safely saf

Physical examination revealed him to be normal. He stood five feet ten inches tall, weighed 190 pounds. His voice was slightly hoarse. Neurologically, he was negative; his vision was found adequate when both eyes were used, though a trifie subnormal when the eyes were tested individually. Death percention and color vision were good. He was thoroughly familiar with the traffic laws

An inspector from the Police Department's license bureau accompanied T-102 on a driving test. He performed according to the requirements of the law, although ... mark this! ... making turns violently, blowing his horn excessively, trying to make pedestrians and drivers move out of his way, "thus showing no consideration for the rights of others."

THIS check was by no means conclusive. It demonstrated the man's ability by to drive, but beyond that ability lay an attitude which Canty explored (urther. He took T-102's psychiatric history. He asked many questions designed to bring out that attitude and reveal his level of intelligence. He studied the record Here is what Canty found.

record. Here is what Canty found:
During the 15 years which T-102 had
lived in Detroit, he received 287 tickets
for various traffic violations. "Minor
violations," explained the subject nonchalantly, as though these infractions
had no significance since he had injured
no one. That was only the beginning.

Many motor-car accidents are caused by thoughtlessness and a disregard of the rights others. Carried to extremes, such irresponsibility will become "driving lunary"

We'll skip the details, and come to the important point. Canty gave T-102 an intelligence test, found him to possess the intelligence of a nine-year-old child. Further, his intellectual weaknesswas complicated by his conviction that laws were made to beat, not to obey.

Canty finished the job, passed his conclusions along to Lowell S. Selling, M.D., clinic director, and here's what Dr. Selling wrote Judge Maher

"While this man is certainly not insane in the conventional sense, his conduct is as unpredictable and dangerous as the usual insane person's would be. for he has no more consideration of the rights of others than one who suffers from an actual serious mental disorder. We might call him a 'driving lunatic' because of this irresponsibility. The fact he has had no previous accident record is a matter of luck, and he is bound to get into serious trouble in the future if he drives. In fact, he has continued to drive although he has had no license. Finally, we consider T-102 the most dangerous man to have been examined in the last 200 cases, and, of course, could not indorse the granting of a license to him."

And, of course, Judge Maher refused T-102 a license. Which concludes our interest in T-102 as a case, but not as a symptom.

How many nun-year-old mentalities step on throttles and guide their motor cars through traffic, menacing life and property? To what extent do intoxication, emotional instability, manise depressive psychosis, pilipsy, faulty mental attudes in general which may be classed as insanity contribute to the appalling total of deaths and broken bodies?

No one knows the precise cause of

Alan Canty, whose work in psychotechnology largely largely forms the basis of the present article, is shown, at the lower left of the photograph at right, operating the reactrograph. With this device it is possible to test the reactions of drivers and hence arrive at conclusions regarding mental attitude

all accidents, because few accidents are investigated thoroughly enough to reach the causes. Then, too, several factors usually are involved. Defects of highway and vehicle, actions of pedestrians and drivers—these contribute. But the driver, 'defective in much or body,'' according to the National Safety Council, is the most important element.

How may these wholesale killings and myuries by hundreds of thousands be halted—or can they? Traffic safety drives often are accompanied by increased killings. Where, then, lies the remedy? In psychatric surveys? Do these surveys adequately reveal the "smart alecs," the "show-offs," the lunatics—borderline and real?

"Traffic accidents largely represent a disease," according to Canty, "and we seek the cause."

Detroit is finding the answer—by measuring human aptitudes regarding motor-car operation. Here street conditions are reproduced in the laboratory, and standardized tests evolved by Dr. A. R. Lauer, of Ohio State University, Dr. Morris S. Viteles, at the University of

Pennsylvania, Dr. Harry R. De Silva, of Harvard's Bureau of Street Traffic Research, Charles S. Myers, at the National Institute of Industrial Psychology in London, and Canty bring to light some surprising facts.

One night in late June, for example, a 51-year-old man made a left turn, and, failing to straighten out on the right struck a car approaching along his left. Not much of an accident, but the police, trained to look for unusual behavior, decided to investigate carefull.

"Pretty tight, aren't you, buddy?" one policeman asked.

On the way to the station, the prisoner admitted he could "feel" the effects of a few drinks. At Judge George T. Murphy's request, Canty, put this man, now T-217, through the paces and learned he was suffering from hypertension, had an artificial left hand

and a hernia on the left side of his body.
"Extremely explosive, aggravated by
many years of chronic alcoholism,"
Canty reported. "Suffers inferiority
complex. Very dangerous."

Oddly, T-217 agreed.

"Better put me on probation for six months and take away my license before I kill somebody," he urged.

Canty accepted the recommendation, and Judge Murphy forbade the gentlepan ever again to touch the wheel of a motor car, adding: "We have no sympathy for drunk drivers."

Why revoke a man's license just because his car his another? The accident, as it happened in this case was not the underlying reason. True, the driver had been negligent; furthermore, the happening was symptomatic of perhaps a more tragic collision. Detroiters value their lives. Their judges and psychologists propose to protect them.

T-217 admittedly had had a few drinks, but T-39 was cold sober when he smashed the trunk of a car whose driver had halted for a red light. Now, T-217, remember. was 51 years old, and T-39, it developed, had barely turned

"I pulled up, but my foot must have slipped off the pedal," T-39 told the police, who didn't like his excuse, and booked him for reckless driving.

"The guy must have been talking to his girl friend," the officers reported to the desk sergeant.

T-39 faced Judge Murphy and repeated his story. "Besides," he added, "damage was only seventy bucks."

This time, perhaps. But what about his next accident, and the next? The boy may have been entertaining his Number One Flame, but, while of average intelligence, Canty's probe revealed these additional significant facts shout him.

History of venereal disease, coarse tremors of facial muscles and fingers, considerable motor incoordination, alcoholism, slightly defective vision

accomment, signity detective vision.

Canty did not stop here Perhaps some of these factors were in themselves effects, and not causes. As he proceeded with his examination he uncovered other facts of even greater bearing on that simple crash.

""HIS father," he found, "he a chronic maleoholic, unstable and rritable. His mother obtained a divorce when he was three, and went to live with a sister who was operating a "blind pig." The boy lived in several boarding homes and was a problem child in several schools. He admits having been arrested three times for being drunk, and recently was held in the Psychopathic Ward of the Receiving Hospital after taking an overdose of barbutal.

T-39 had disintegrated, and it was not entirely his own fault. What to do with him?

"Your youth and attitude," Judge Murphy told him later, "make you worthy of help."

T-39 went on probation; his license will not be returned until he demonstrates to the court's entire satisfaction that his mental and physical health make him once more fit for the high-

Traffic authorities, judges, and psychologists have no desire to diminish the number of drivers. They wan thonestly to protect the public—you and me-by adjusting drivers with correctable defects and eliminating from the streets and highways those too severely maladjusted.

This is the reason for Detroit's Paychopathe Clinic, which is a department of the Recorder's Court. It was established for the sole purpose of examining individuals referred by various courts of the city. To it come those who are convicted of traffic felomes, and those who by their behavior subsequent to arreat lead authorities to think paychiatric examination is indicated. All have been found guilty before Carty gets them. Upon his recommendations rest their punishment and rehabilitation,

If this article seems to harp on artitrade, the emphasis is wholly destrable, for artitude of the driver toward the law and his fellow man holds the key to success for this newest cross between judge and detective—the psychotechnologist He never knows at the outset whether he's dealing with a temporarily unstable intellect or a dangerously in same driver. Nor is he interested—officially—in what he finds.

T 398 (you will note that Canty identifies none of his subjects, for unofficially he hopes each will somehow

Arrows raised 1/4 of an inch above the surface of the road, some painted white and some black have been installed on this California highway is an endrayor to redure the state's accident rate

escape the damning implications of lunacy) seemed mild enough when picked up for speeding. His tone changed in the courtroom "These birds," indicating the officers.

"These birds," indicating the officers, "want to get me. They've jimmied up my speedometer. Honest, your honor, I'm not guilty."

But in the quet of the laboratory, the 39-year-old speeder unwittingly gave up an entirely different story. Not only had he been in the hands of a psychatrist for treatment, but he was at that very moment suffering from a severe form of insanity. Crazy—and at the wheel!

No jail sentence for T-398. Eloise Hospital got him, where he will be denied all contact with the motoring public until death or medical science separates his physical body from his unfortunate mental deficiencies.

SUCH cases could be multiplied many fold were there such men as Selling and Canty on the job from Sandy Hook to San Diego, from Jacksonville to Jackson's Hole. Every community has these cases, yet so far there is only this fragmentary record of their criminally irresponsible driving.

More than 30,000 likely will perial in motor-vehicle accidents in 1939—many of them vettins of men like T-102 and T-398. Make available to Canty the necessary constellation of factors upon which he builds a decision, and he'll soon tell whether John Jones. or you, or me, is a safe bet behind the steering wheel. Gern a thousand Cantys, with scores of thousands of "attitudes" explored each year, and we'd have safer driving, need a hundred new hospitals for the insare-or both.

Street conditions, in model form, are reproduced in Detroit's Psychopathic Clinic, and standard tests are used to bring out facts about drivers' fitness

Research On High Pressures

In the past few years "extreme pressure" has gone out of the realm of a scientific curiosity and has become a tool in the solution of practical problems.

In spite of the fact that, until recently man was not able to develop pressures in the laboratory as high as 1,000,000 pounds per square inch, such pressures frequently occur about us in our everyday experiences. Pressures of a few hundred thousand pounds per square inch are occasionally produced in the hypoid gear in the normal operation of an automobile, in roller or ball bearings, under the wheel of a glass cutter, when the bullet of a high-nowered rifle strikes a solid object, and in many other cases where two hard objects strike each other. They are, of course, confined to an extremely small space, and have a very short duration Such extreme pressures in liquids or gases are much less common, but even gas pressures of nearly 1,000,000 pounds per square inch probably occur every day as particles of meteoric matter, traveling with a velocity of 30 miles per second, collide with the very light upper layer of the earth's atmosphere.

Recently an experiment was carried out in the high pressure laboratory of the Research Foundation of Armour Institute of Technology in which a pressure of 1.5000.00 pounds per square inch was developed. This was the highest pressure ever produced experimentally in high pressure investigations. The pressure at the center of the earth is estimated to be about 3,200,000 atmospheres, or only 32 times as great as the maximum pressure that has been produced in the laboratory.

This increase in range of artificial appressures may clear up many puzzling questions which have formerly been considered impossible of solution. Very the considered impossible of solution. Very the considered in the past in the solution of everyday problems of a seince and industry, but they are rapidly assuming a place of increasing importance, and in such experiments lie the answers to many questions of the greatest commercial importance.

A brief survey of the work that has been studied by means of the high pressure equipment now in the high pressure laboratory of the Research Foundation of Armour Institute of Technology will serve to show the great diversified application of such investigations.

A Curiosity of Science is Proving to Have Direct Practical Bearing on a Large Number of Industrial Problems . . . Examples of Promising Applications.

By THOMAS C. POULTER, Sc.D., Ph.D. Scientific Director of the Research Poundation of Amount in the Company (Philipse)

The work was started in an attempt to study a reported effect of pressure upon the chemical reaction of sulfuric acid on zinc to form zinc sulfate and diberate hydrogen. This investigation was carried to a pressure of 30,000 atmospheres, during which it was found that the effect which we set out to study din out exist. In the course of the investigation we found many interesting things, including a little known chemical reaction of hydrogen on sulfuric acid to give hydrogen sulfide and water.

Other chemical reactions were investigated under extreme pressures, such as the reaction between sugar and water. The rate of this reaction was found to decrease with increase in pressure

From the information gained as a result of our previous work, new pressure equipment was developed in which it was possible to carry on experiments in cylinders with glass, quartz, or diamond windows, which will withstand pressures of one half million pounds per square inch. In connection with this development many interesting phenomena were observed, such as the ability of glass or quartz windows one quarter inch thick to be bent to a radius of curvature of four inches as many as ten times before being hroken.

The development of these windows made it possible to study the effect of pressure upon the manner in which a beam of light, which is vibrating in one plane, is rotated as it passes through compounds which tend to rotate this plane of vibration or polarization. This effect was to increase the rotation of all compounds studied, some of them being increased to three fold their normal value. Both materials which rotate to the right (dextro-rotatory) and to the left (levo-rotatory) were investigated. This provides a method of studying the progress of such reactions while the materials are under pressure.

The windows also made it possible to study the phosphorescence of zinc sulfide, and it was found that the effect is to decrease the intensity of the phosphorescence by a factor of one half for a pressure of 30,000 atmospheres. It was also found that a rapid change in pressure would produce a bright glow of the zinc sulfide Aside from the intensity, the fluorescent and phosphorescent properties of zinc sulfide were very little affected by extremely high pressures. It, therefore, provided a convenient method of studying the effect of extreme pressures upon the radioactive decomposition of various materials by actually observing scintillation. These measurements confirmed the negative results of similar investigations by other observers using quite different methods.

Further investigations made possible by the pressure windows were the deter mination of the effect of pressure upon the index of refraction of certain liquids. This investigation showed that the theoretical relation developed by Lorenz-Lorentz for the relation between density and index of refraction holds for those substances investigated.

THE quartz windows were further trailized in making absorption spectra measurements of the effect of pressure upon the compressibility of the neodynium atoms at the various electron energy levels.

The effect of pressure upon living organisms has been studied, with the observation that 12,000 atmospheres are necessary to kill bacteria, but as the complexity of the living organism increases, the pressure necessary to destroy life decreases. Because of this selective effect of pressure in killing living organisms and the relation that exists between the pressure required and the size of the organism, it is possible that this may lead to developments of far-reaching importance in combating certain diseases. Some small forms of marine life about one fourth inch in length, such as hydra and planaria, were found to withstand pressures of from 10,000 to 20,000 pounds per square inch without any serious damage. The effect of high pressures was to precipitatesome of the colloidal constituents of the organism, and a study was made of the precipitation of other colloids, such as suffur, silver, gold, ferric hydroxide, molybdenum blue, and prussian blue. Some colloidal materials are precipitated by the comparatively low pressure of 100 atmospheres, whereas others are only slightly affected by pressures as high as 17,000 atmospheres.

THE electrode potential of the hydrogen electrode was investigated under pressures up to 30,000 atmospheres and the voltage of the Weston Standard Cell up to 12,000 atmospheres. The effect of pressure on both of these is of a rather low order of magnitude.

The effect of pressure upon the pene tration of water and numerous other liquids into glass and metal surfaces has been investigated with some very interesting results. Water was found to penetrate in considerable quantities to a depth of several millimeters into glass in only a few minutes' time The penetration of alcohol and ether is somewhat less, and such liquids as paraffin oils, glycerin, and so on, penetrate scarcely at all A similar effect, but to a considerably lesser degree, was observed for the penetration of liquids into metals. The penetration of gases into metals, of course, is more rapid than that of liquid and represents a problem of considerable industrial importance, particularly in the case of penetration of hydrogen into steel whereby the tensile strength of the steel is reduced to less than half its original

The normal dissociation of steam into hydrogen and oxygen, and the subse-quent removal of the oxygen by its reaction with the metal of high-pressure steam lines, particularly under conditions where a high superheat is used. presents a problem of the utmost importance in the high-pressure, high superheat, steam installations that are being used at the present time. It has been shown that considerable quantities of hydrogen are continually escaping through the walls of the high-pressure, high superheat, steam lines, and this subject should be thoroughly investigated to determine to what extent this is affecting the tensile strength of the metal of the steam lines. If this effect is cumulative, as is the case under the conditions of many of our experiments, it might very well become a problem of great importance in high superheat steam insulation, if not indeed a limiting factor in the industry. We have found that this effect is not only a function of the temperature and pressure, but is also affected by the composition and heat treatment of the steel. It is, therefore, a combination high pressure and metallurgical investigation.

Other fields which have been investi-

A pressure of 580,000 pounds per square inch has been developed in this cylinder (between the four large tension bolts) which contains a glass window meither end for internal observation

gated are compressibility of liquids and solids, the effect of pressure upon the viscosity of liquids, and in some cases the change of state, or even transitions from one crystalline form to another.

A brief summary of the effect of presore upon the properties of matter will reveal some very interesting facts. The following characteristics for liquids and solids are all affected by pressure: density, volume, index of refraction, electrical conductivity, thermal conductivity, magnetic permeability, delectric constant, optical rotation, chemical reactivity, solibility, phosphoreseence, fluorescence, phospical strength, specific heat, latent heat, permeability to gases and liquids. and viscosity,

If we consider all but the last two items on this list, we will see that the effect is anywhere from a small percent up to certainly less than a factor of ten.

But now let us consider the last two items. The permeability to gases and liquids may be of the order of magnitude of many thousandfold, and the coefficient of viscosity of many lubricating oils is increased by as much as 200,000,000 times their value at atmospheric pressure. Some liquids are affected comparatively little by pressures of 400,000 pounds per square inch, whereas some oils acquire a hardness between that of metallic lead and metallic copper. It is, therefore, probable that the lubricant of the future, where extreme pressures are involved, will be a liquid little affected by pressure. This will serve as a carrier for a different material which becomes sufficiently hard under pressure to serve as the lubricant. It is therefore our belief that the permeability to gases and liquids and the effect of pressure on viscosity are the two characteristics that will represent the most fruitful problems for investigation, and certainly are the two that are most likely to produce noticeable effects in industrial processes involving high pressures. Investigation of the permeability of gases and liquids has already been discussed and the viscosity investigation of lubricating oils under pressure probably represents one of the most promising investigations to be carried out in this

Noise Control

If you attend the New York World's Fair and enjoy your visit to the Perisphere, that huge spherical structure which houses "The City of Tomorrow" exhibit, you can credit your pleasure to the new science of noise control.

This Perisphere shows what a sectinific attack on noise can accomplish. Without aconstical treatment, this 180foot diameter room would be a reverbearting chamber of horrors. As it is, voices, a symphony orrhestra, and movun from pachinery are housed peaceably and you hear pleasant sounds rather than a silly symbolomy of noise.

Noise control is a necessity, not a fad The clatter of machines, the din of office equipment, produces deafness and nervous disorders, while the high noise level of modern civilization in all its phases lowers human efficiency and happiness. We know this to be true because controlled tests reveal that employees make fewer mistakes and produce more when their work environment is made quieter, and because the public responds quickly to noiseless products. Thanks to noise control, we enjoy automobiles which really live up to that old slogan, "No Noise But the Wind"; we go to the talkies because we can hear the actors free from the sound of film production and background disturbance; we can fly across the continent without cotton in our ears.

Industry benefits directly from the in crease in sales which follows quickly upon the silencing of a product, but that is by no means the only advantage derived from attacking noise. MachinNecessity, Not a Fad...Controlled at Source ...Stopped or Damped by Scientific Design... Improved Efficiency, Calm Nerves, Less Deafness

By PHILIP H. SMITH

ery which has been re-designed to reduce noise is often more efficient and frequently cheaper to produce than its raucous predecessor. Furthermore, the study of sound has led to the development of machines which employ sound for production control and product inspection, thereby lowering cost

The new science has evolved from many years of study into the nature of sound and its transmission. Work with the telephone, and later with radio, has been contributory because investigators treated sound as a phenomenon to be controlled in the interest of creating wanted sound and subdumed.

or eliminating the unwanted Out of all this has grown a fairly definite procedure for tackling all noise problems.

Designed to be as silent as possible, the fast-runkler possible, malmost human" office machine at the right is further silenced by being mounted on rubber footings. Likewice, the clatter of the wire machine below is dampened by footings which absorb vibration and therefore some of the noise. Insert shows the mounting of rubber and steel

Every control problem has two phases. The first phase involves the measurement of sound. Two types of microphones are used for this: one is sensitive to velocity or perticle motion, while more commonly used is sensitive to pressure. The electrical current establishes the electrical current of sound which can be analyzed in terms of frequency and intensity

This first phase is known as the diagnosis. It is essential to the second phasewhich is the treatment. Most noise is made up of several sounds and the diagnosis weeks to sort out and identify the

varous components. Customarily, the specialist attempts to pull down the highest component and then proceeds down the scale until a level is reached which is considered satisfactory. His achievement is recorded as a lowering of decibels; that is to say, in a reduction of watts per square centimeter of acoustic nower.

The engineer's skill centers largely in his ability to bridge the gap between analysis and application; in relating noises to their origin. Once he knows what offends and to what degree, he finds it relatively easy to choose between modes of treatment. Instrumentation alone will not do the job. Ears and past experience must be employed to interpret because noise control has not yet been reduced to a book science.

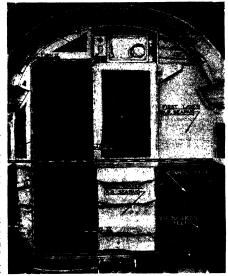

The engineer regards noise as a fact rather than as an abstraction. The elimination is warranted only when there is an irritation to the human system. He seeks, therefore, to uncover the components and reduce them to a non-rritating level. His interest is in making life more bearable, rather than in banishing noise per se.

The fact that noise is always relative and that this relation is an integral part of the control problem is well illustrated by reference to the automobile. The seasoned car owner may recall the experience of coasting with a dead engine. to become conscious suddenly of many annoying chassis and body rattles hitherto unnoticed. With the engine sputtering again, the rattles became lost in the general clatter Engineers met a similar experience when they undertook to silence automobile engines to make them what we now enjoy. When the engine was made less objectionable other noises became prominent and so treatment was carried from one unit to another to achieve an overall benefit Similarly, air-conditioning equipment suitable for city buildings has been known to be unbearable when installed in suburban dwellings where the background noises were lower

WHILE the passenger automobile illustrates the general problem of noise control it is by no means representative of details. Every noise problem tends to be unique, and to demand its own particular method of solution once it has been analyzed. The silen cing of auditoriums, for example, involves the exclusion of street noises as well as the treatment of sounds gen erated within the structure. If the entertainment sounds are to be pleasurable, the specialist proceeds to determine the timing, direction, and strength of noises and to select the proper material to subdue the unwanted sounds without impairing the quality of the voice or instrumental performance. In early days of noise control when the science was less exact, sound-proofing was often overdone, with the result that the entertainment sounds were rendered

Thick pads of glass wool next to the skin in the curved fuselage ceiling of a Clipper plane

Sound-proofing installation in the forward cabin wall of an airliner. Several kinds of fibrous sheets are built in. They include a coarse paper and felt

Irieless, especially in radio studios The afore-mentioned Perisphere is really a unique auditorium calling for special treatment. It has the curved ceilings and walls surfaced with a soundabsorbent bacrd made of shredded wood fibers and backed by two other absorbent materials placed in alternate squares. Some eight feet behind this surface treatment, a mineral wood prod-

uct placed between the structural steel girders and lining the inner surface of the sphere's outer shell, traps whatever noises get past the inner wall and prevents reverberations from annoying the audience.

Often an important factor in the silencing of public buildings is attack upon air conditioning and operating machinery. Sometimes it is necessary to dampen blower noises, and to line air ducts and re-design outlet grilles to reduce the sound of rushing air. More and more the practice is re-

sorted to of suspending heavy operating machinery on rubber-in-shear to prevent the transmission of sound vibrations.

It is possible to contrast the problem of noise control in the treatment of structures by citing instances of silen cing a telephone booth and an aircraft engine test building. By studying the course of sound travel a very interesting booth has been developed which has no door and, therefore, does not get stuffy or become a steam bath on hot days. Sound which enters the open side is trapped by absorbent wall surface materials, while the exterior is treated to reflect and disburse the bomhardment of unwanted noise. In the case of the aircraft test room, silencing the engine itself was out of the question as the purpose of the test was to take measurements running under normal operating conditions. Here, the building housing the engine was made as sound-proof as possible while the exhaust was carried by vertical stacks to a great height to be expelled with little annoyance to the investigators as well as the surrounding neighborhood.

Where there is motion there is ant to

be noise and thus transportation equipment of various types has been receiving a great deal of attention Recently. a silenced train was placed in operation on one of New York City's subways to demonstrate very convincingly what can be done in the way of insulating, absorbing, and otherwise dampening out noise to make travel more comfortable. Even track has been tackled from the noise elimination standpoint. In this same city, rubber tie plates have been tried out under normal operating conditions to determine the cushioning effect of placing the rails on rubber While a measure of comfort is provided for passengers by this new device, the principal advantage accrues to adjacent building structures and to rails and rolling stock. About 90 percent of vibrations is prevented from reaching the buildings, while the life of rails and rolling stock is substantially lengthened. It is a little early to forecast an overnight adoption of rubber tie plates, but there is a strong likelihood that they will come into use where the greatest damage is inflicted by impact, such as on curves and on bridges.

RUBER suspension plays a very important rôle in the silencing of modern trolleys, buses, and streamlined trains, but much progress remains to be made. Noise control got its foothold in the luxury end of transportation and has still to make its real contribution to mass transportation vehicles via the road of silent design.

Apropos of rubber suspensions, a case can be cited which illustrates how easily the amateur noise controller can be led astray in his quest for silence. It is common practice to suspend heavy machinery at four points, although three-

Installation in a school of a Celotex product which effectively absorbs unwanted sounds, prevents reverberations and echos. At right-Johns-Manwille sound deadening material being packed into the cushioned floor chairs which are part of a special "floating" construction that efficiently controls all noises efficiently controls all noises.

point suspension is often more satisfactory because it insures an even distribution of weight at all times Knowing the efficacy of tubber suspension, one practitioner concluded that the more rubber the greater the absorption and placed a channel or frame of rub-

her under a machine in place of four blocks. It failed to silence because of the sealed-in area under the machine which permitted no escape of air as the machine rose and fell mutuely in operation. In short, the vibrations were transmitted to the foor acting as a diaphragm under the action of compressing and decompressing.

Noise control engineers have practiced long enough to swod such mistakes; they know that can add mnot be done. In early experiment, and in automobile it was discovered that the mura silencing to be had by mulating chassis from body by means of rubber mountings was impractical. The advantage derived from the extreme quiet was offset by the uncomfortable sensation of body and chassis parting company momentarily on turning corners; thus a compromise was reached and revort made to other silencing orgatices.

If it is permissible to call a tank and

a submarine transportation vehicles, they can be mentioned here as examples of highly important noise control work, even though the details are lacking. The interior of a tank is a poor place for survival at best and its operation has been hampered by the terrific din which military authorities now seek to subdue. At least one European Power is hard at work eliminating the noise from submarine operation to render the vessel more immune to discovery by sound detectors in the hands of the enemy

It is now a well substantiated fact that silence can be had at less expense if built into a product, rather than by removing noise after manufacture. Often it costs less to produce a quiet mechine than to manufacture a noisy one and there are innumerable examples of noise control own which has led straight to lower production cost, more efficient operation, and larger sales of the product. One noisy element in an otherwise well silenced product may be a large obstacle toward its wide use.

Consider for the moment the case of a street car which emitted a noise like a siren. When analyzed, it was discovered that the frequency of the sound was destricted with the number of revolutions of the ventilating fan multiplied by the number of blades. With this clue the nabse was tracked down and eliminated by allowing sufficient room for the rushing air to pass between blades and the metal outside ribs of the fan.

Outstanding among the examples of built-in silence is the modern commercial transport plane. One will recall the pioneer days of commercial flying when only the application of cottom to one's ears made transportation bearable. Today, cotton is a surplus commodity in aviation because the plane producers called in noise engineers to check design features in their relation to noise creation and transmission. The silenced plane did not arrive overnight. The first.effort, that of trying to find a sound-proof material to wrap around the plane, proved firtilizes. Materials satusly different secustical needs and these that to be differentiated and evaluated as to their insulating value. More important, the sources of din had to be located and classafeed in the order of their importance, then tackled separately and jointly, because it was an other discovery that silencing one component accomplished little; all contributory sources had to be treated.

By far the worst noise offender in an airplane is the propeller, and not the engine as might be expected. Engine exhaust ranks second and engine clatter third. Improvement came by increasing the distance from the tip of the airscrew to the fuselage and designing so that baggage or utility rooms would lie in line with the propeller; likewise exhaust was led to discharge as far from the cabin as possible. Engines are, of course, sources of vibration and, to overcome some of the disagreeable effects, flexible mountings were developed. Then, to improve conditions within the plane, the floors were suspended so that they virtually floated and windows were given flexible mountings in rubber.

most every instance where the result is outstanding.

Thus far we have made no comment upon sound deadening materials. This is wholly intentional; acience and technique precede materials and their application. Acoustical materials number in the thousands. They embrace a host soft fibrous substances in countless forms, core, plasters, different forms of number, various terrals, almost without end. Each has almost without end. Each has at the own peculiary comments of the comment of the propose materials, almost without end. Each has at own peculiar combination of properties and the choice for any application requires exceptione and judgment.

Note control is in its infancy despite the rapid advance made within recent years. One has only to jot down a partial last of all the products which have not been selenced to reach his own estimate of the future. At the same time it would be a gross oversight not to include the utilization of sound for production control and inspection of products This is a phase and a mighty important one of the noise-control science. It promises rapid development because the few things already accomplished demonstrate a dollars-and-cents -aving more

An outstanding development for subway car noise control a rubber spring to be mounted on the axles. It is constructed in the shape of a hollow cone with flanges inside and out, and is split through for mounting between the truck and car

Air ducts in air conditioning systems would carry the noise of motors and blowers through an air-conditioned building were it not for the soundabsorbent lining of the duct, in this case Airacoustic sheets immediate and obvious than that derived from silencing noisy products.

Just as the electric eye has been focused upon productive purposes, so the electric ear has been turned toward industry. The ear is now being employed to regulate the flow of raw material to a ball mill. This device increases ball mill efficiency by 10 percent, while a similar percentage reduction has been made in power consumption. If gains are borne out consistently, the electric ear will undoubtedly come into use for the grinding of such materials as clay, limestone, silies and corent.

AMONG the instruments developed for product inspection which base on sound for their operating principle, there is one which checks over cans of condensed milk to locate those in which a bit of solder has broken loose to create spoilage. There is another which tests for the quality of abrasive wheels. A good wheel gives off a definite note which rings for a certain length of time when it is struck, and it is quite simple to check the pitch and duration of this sound. A third device tests for gear tooth contour by the sound of gears in mesh This last device is extremely important as providing still another means for checking gears so that the modern automobile can be operated without an annoving hum at various speeds.

This harnessing of sound opens up an entirely new field and we may expect development here to run parallel with those which endeavor to dimmate or lower sound to non-irritating levels. Before noise control could be undertaken in a serious way as a specialized teaterprise it had to produce tangible results at a reasonable cost. Those results have been accomplished and the time has come when the specialist comes close to saying: "I can kill so many decibels for so many dollars." This gives the go-shead sign to industry

Photographs sourcesy Boeing Aircraft Co., Celotex Corp., Douglas Aircraft Co., Inc., B. F. Goodrich Co.: Johns Manyille Corp.

The foregoing gives but a brief list of noise control elements in modern transport design. It does serve, however, to emphasize the principle of "before" rather than "after" treatment in design, because the accomplishment has been such a large factor in abetting the progress of commercial aviation. The advantages are evident for all to appreciate who fly. There are on the market other products less striking that have been favorably influenced by the patient and thorough work of noise control engineers, notably vacuum cleaners, mechanical refrigerators, and garbage dump trucks, while a good beginning has been made with business machines of many types. It will be found that quiet has been built-in rather than achieved through noise reduction in al-

Our Galaxy Re-Measured

THE most powerful method we have for sounding the depths of space depends upon variable stars of the Copheid type. The remarkable relation between the periods and the real brightness of these stars, first detected by Miss Leavitt at Harvard, some 30 years ago, has been fully confirmed by later studies.

Measured by photographic effectthat is, in violet light—a star of this sort, with period 2½ days, is 350 times as bright as the Sun. For a period of five days the brightness is 550, for ten days it is 830, 20 days, 1500, and, for a 50-day period, 2500 times the Sun's. If then we can find the period of variation which is not so hard if we have enough photographs to work on—we know how bright the star really is; and, knowing how bright it looks, we can calculate the

Useful as this relation is, we are still in ignorance of its physical cause. We have very good reason to believe that variable stars of this type are pulsating -alternately expanding and contracting -and the theory of these changes has been worked out in considerable detail But this theory depends on the laws of gravitation and of gas-pressure. It tells us that a star pulsating with a given period must be of a certain density (lower for longer periods), but places no restriction on its size. The observed fact that stars of a given period (and density) have all the same brightness, and hence the same size and the same mass, must depend in some way upon the manner in which heat is generated from atomic sources inside the stars

WE are presty sure now that the heat is liberated evenly at the time when the star is smallest, and dark in mide, which is made, and the star is smallest, and the star is the internal structure of these stars is they queer, they cannot be hot enough made to utilize the process by which Bethe has explained the shining of the main sequence stars. We may know soon what cless happen—in fact, promising suggestions have been made by Gamow—but we cannot be sure.

Fortunately, we do not have to wait to understand the process in order to use the facts. Were it not for one obstacle, we could map out all the nearer portion of space, up to 1,000,000 light years or more. But there is something really in our way—great clouds of thin haze in space which weaken the light

Galactic Rotation Effects, Interstellar Absorption and Certain Dynamical Constants of the Galaxy Have Been Determined from Cepheid Variable Stars

By HENRY NORRIS RUSSELL, Ph.D.

Chairman of the Department of Astronomy and Director of the Observatory at Princeton University Research Associate of the Mount

of the stars behind them, and make them look fainter than they would otherwise appear. Many of these clouds are sharply defined, and show conspicuously against the background of the Milky Way—but there is an increasing weight of evidence that these are only dense portions of a vast thin log which extends along the plane of the Milky Way to

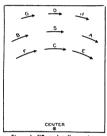

Figure 1 Effect of stellar motions

enormous distances but only a little way on each side of it

When we look at an object, such as a sprain hebila, which he saf nou'd the galactic plane, our line of sight soon escapes from this dust-haze and enters intergalactic apace, which appears to be almost perfectly clear. But distant objects in the galactic plane are much dimmished in brightness, even though the mobilities of the distance of the mobilities of the distance of the course of the distance of the distan

Simple and convuncing proof of the existence of this absorption has recently come out of the admirable work which Dr. Joy of Mount Wilson has done in measuring the radial velocities of Cepheid variables. Since these objects can be seen at great distances, they should be particularly suited for our use in

a study of the rotation of the Galaxy. Our more persistent readers may re-

call a discussion of this some months ago [December, 1937 .- Ed.] of which the main point may be repeated here. Suppose that the Milky Way is in rotation about a great mass of stars at its "Center" (Figure 1), and that the Sun S is moving in a circular orbit, at a speed represented by the arrow. Stars at A and B, ahead of it or behind it in its orbit, will be going at the same speed, and neither receding from us or approaching. A star at C, nearer the center, will be moving faster-like a planet nearer the Sun. Its motion will be crosswise, and its distance will not change: but one at E will be running away from the Sun, and receding, and one at F overtaking it, and approaching. Stars on the opposite side will be moving slower than the Sun. There will be no change of distance at D. but the Sun will run away from G, and catch up with H The net result is that stars in two opposite parts of the galactic circle will be receding and those in the intervening quadrants approaching. The greater the distance of a star from the Sun, in a given direction, the greater will be the speed of approach or recession; indeed, this will be proportional to the distance, until the latter becomes a considerable fraction of the distance to the center (when things get more complicated).

THE Sun as not moving in a precisely Licitudes orbit; but this is easily allowed for. For the stars in the general vicinity of the Sun—asy 100 lightly-sers—the differences from circular motion will average out. Hence the motion of the Sun, relative to the general average of these stars, will represent its difference from motion in a circular orbit about the galactic center. It is fairly asset to find this motion, and to allow for easy to find this motion, and to allow for

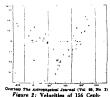

Let us now return to the Cepheid variables. Their observed velocities must be corrected for the "solar metion" just described, and also for the motion of the surface of each star, arising from its alternate expansion and contraction. To eliminate this it is necessary to make many observations of each star, distributed at different phases of the variation, so that a curve may be drawn to represent the changes in velocity—from which a true average value may be derived.

This has made Dr. Joy's work very laborious, as, on the average, a dozen or so plates were needed for each of the 156 stars on his list

When it is added that more than half these stars were fainter than the tenth magnitude, and some of them below the 14th, we may begin to realize what an enormous amount of diligent observing has gone into his results.

When the normal velocities for each sar are cleared of the effects of motion of the Sun relative to its neighbors, and pioted against the galactic longitude, a very marked double oscillation is seen (Figure 2). The plot looks rather tagged, which was to be expected, as stars at very different obstances, with different rotation-effects, have been combined.

If the stars are sorted out according to their distances—calculated on the assumption that there is no absorption of light—it is found (Figure 3) that the nearest stars show only a small effect, and greatly exceeding the deviations for midwidual stars (which represent the differences of their motions from circular orbits). For the next group, the amplitude is great, and for the two trainets groups, the rotation-effect great-

eids according to galactic longitude

ly exceeds the individual motions of the

No more convincing proof of the salactic rotation could be desired; but there are still complications. The average distances for the four groups, calculated without absorption, come out 1700, 5000, 10,400 and 20,000 light-years; the half-ranges of the effect are 10, 22, 29 and 38 kilometers per second—and by no means proportional to the distances, as the theory demands. The simplest explanation for this is that there is a general hazy absorption

of light such as has been described above. This makes the more distant stars look fainter and leads to an overestimate of their distances. By "cutand-try" methods—assuming various values for this absorption, calculating corrected distances, and seeing whether the results run in proportion to the observed rotation effects—Dr. Joy finds that a good agreement can be reached with an absorption of 0.85 magnitude per thousand parsecs, or 0m.26 in 1000 light-years. The average distances for the four groups then come out 1400. 3500, 5400 and 7500 light-years. For the nearer stars the effect is not great, but for the last group it is very serious There can be little doubt that this result is substantially sound, for investigations based on quite different data indicate about the same amount of absorption.

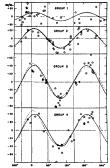

Accepting this value, it appears that the depth to which we can study the structure of the Galaxy with the aid of Cepheid variables is limited. Even a very bright Cepheid, of period 50 days, would appear of the 16th magnitude at a distance of 20,000 light-years, and of the 19th at 30,000.

OUR only hope of finding more distant objects lies in the fact that the obscuration appears to be not uniform, but patchy There are dense clouds in places, thinner ones elsewhere, and nearly clear regions. The value given above is a sort of general average. In heavily obscured regions we should not be able to see as far; and Joy notes that there are no Cepheids in his list at calculated distances greater than 4000 light-years within 20 degrees on each side of the galactic center in Sagittarius, where the obscuration is known to be heavy Even here, though, there is a chance that there may be gaps between the great clouds, which provide "windows" through which we may see some much more distant objects. A careful detailed study, region by region, is required to detect these, and promising results have been obtained at Harvard.

results have been obtained at interval to a it is only when we look right along the galactic plane, flatwise through the absorbing haze-layer, that we get into so much trouble. Joy concludes that this layer is 1300 light-years thick. Light coming in at any considerable angle to tis plane will not have a long enough path in it to be greatly weakened. This assumption of a uniform layer with sharp boundaries is again greatly oversimplified. It is almost certainly irregular in thickness and thins out gradually.

One thing which the Cepheid velocities give accurately is the direction of the center of the Calaxy—of the line S-Center in Figure 1. This is found to lie in galactic longitude 325° 3 ± 1.3—in very good agreement with other determinations. The distance of the

center is much harder to determine accurately, but the figure shows how it can be done. The point B at which a star would neither approach Sor recede from it lies on the circle BSA, so that the single BS-Center will be less than no 90°. If we can determine it, and the distance SB, we can find S-Center. Using the second and third of his groups of stars (which should give the best

From The Astrophysical Journal
Figure 3. Rotational curves for the
four star groups named in the text

values) Joy finds the distance of the center to be 38,000 and 24,000 light-years. The first value should be more accurate, so that he adopts 33,000 light-years (10,000 parsecs) which again agrees with the results of other observers. This is so much farther away than even the remoter Cepheids that no great difference is made in the calculations, when it is taken into account. (Dashed curves, Figure 3, show results.)

When allowance is made for galactic rotation. The outstanding residual anotions of the Cepheids are found to be small—averaging only 11 kilometers per second. As the circular velocity about the galactic center is nearly 300 kilometers per second, their orbits must be very nearly circular. They are very nearly in one plane, also, for the average distance from the mean plane is only 200 light-years as against a probable diameter of at least 50,000.

Only one thing prevents these results from being definitive and final. The southern Milky Way, from Carina through the Southern Cross and Canturus, is below the horizon of Mount Wilson, so that the only spectroscopic observations available in this region are those which have been made with smaller telescopes in the southern hemisphere.—
At Sea, M. V. Britannic, June 30, 1939.

Cuba-Key To Manganese Problem

CUBA today holds what may be the most important single key to America's national security in time of war.

Nine years ago this wasn't true Since then, American capital has developed, in Cubs. America's only nearby source of a raw material vital to our national defense—a dirty looking. sooty ore of manganese. This ore is an absolute essential for the manufacture of steel, the metal that wins wars.

Attention in United States metallurgoal circles has been focused recently on our national procurement problem as regards manganese and other materials essential to industrial operation, by passage of the \$100,000,000 "stockpile". bill, signed by President Rosevelte early last June. This bill, aimed at reducing the "dangerous and costly dependence" of the United States upon foreign sources of "strategic materials," is designed to encourage development of our domestic sources.

American private enterprise has already contributed largely to solution of one aspect of the procurement problem. The Cuban-American Manganese Corporation, a subsidiary of the Freeport Sulphur Company, has developed in Cuba the world's only plant for concentrating manganese ore on a commercial scale by the flotation processwhich means that they did something that metallurgists had for years considered next to impossible. Direct result of this development was that Cuba, which in 1931 provided less than 1 percent of American manganese needs, last year sent us over 25 percent of our total imports for consumption.

THE importance of this development may be fully realized only when considered against a background of facts regarding the properties of manganese, and the tenuousness of our foreign sources of supply. Manganese is not just one of a list of more or loss essential materials. Of all the strategic raw materials, it has been rated Number One in importance by the War Department. Furthermore, there are many graders of manganese ore, and not just any grade will do.

Manganese is the only material which can be used economically as a deoxidizer and de-sulfurnzer in blast-furnace operations at steel mills About 14 pounds are used in making a ton of high-grade steel, and, without manganese, no steel could be manufactured economically in this country. To be of use to

Manganese Vital in Steel Manufacture...We Have None...War Would Cut Down Imports...Cuba Now Supplies Some...Momentous American Achievement

By RICHARD B. CLARKSON

the steel industry, the manganese ore must be of "ferro grade"; that is, it must have a metallic manganese content of about 50 percent.

Although deposits have been charted in 20 states, these are for the most part of such low grade in their natural state as to be virtually useless for steel manufacture. Costs of concentration have for years been considered problishive. Concentrating methods other than the 60state of the the 60sta

Since the war, we have depended for about 95 percent of our supply upon foreign sources, in countries that possess deposits from which high-grade manganese is obtained at exceedingly low labor cost—Russia, India, Africa, and Brazil. Russia has for years been our number one supplier and, in spite of the Cuban development, still is.

As long as we reman largely dependent upon such remote sources for our supplies of manganese, we face our the probability of a dreate curtailment of supply with a flare-up of warm in Europe. Such an emergency would almost surely result in the establishment of blockades at the focal points of trade routes serving warring nations —particularly in and around the Medi-

terranean—through which pass shipments of manganese to the United States from both Russia and India.

In the light of these facts, the significance of the Cuban development may be seen as two-fold. In the first place, Cuba is only 90 miles of Key West and there is little possibility that shipments of manganese from this source could be interrupted in the event of war. In the second place, the rise of Cuba as an important source of so vital a raw material is taken by many as polating the way to possible similar.

development of our domestic sources. The Cuban-American Manganese Corporation was formed in 1932, but work preparatory to its formation began as early as 1930, when the Freeport Solphur Company instigated petrographic studies of ore and rock formations in Cuba. This work was undertaken on samples taken from north of the town of Crast in Oriente province, on the lower slope of the Sierra Madre Mountains.

DEFORE 1930, many attempts had been made by other concerns to concentrate the Cuban ore, but all experimenters had come to the conclusion that the ore bodies were too irregular in occurrence and too low in grade to concentrate. Freport's preliminary investigations of the ore bodies reveals that—in their field to the north of Cristo—there existed some high-grade maneace ore, varying in manganees content between 38 percent and 50 percent. Most of it, however, averaged around 18 to 20 percent—a grade far too low be used by stell manufacturers.

Previous investigators, however, had confined their experiments to the conventional gravity separation method, which operates on the principle that manganese differs in specific gravity from the material with which it is combined in nature. It was discovered by

Freeport that insufficient difference existed between the mineral and the "gangue" material—ditt—from which it was to be separated, to allow efficient concentration. Other previously-attempted methods of dissolving and precipitating the ore were found to be either inefficient or prohibitively costly.

Having cleared away the deadwood of old methods, the company concentrated verge of profitable operation. It was this point in 1925, however, that the United States-Brazil trade pact caused such a drop in the domestic price of manganese that operations at the Cuban-American plant were immediately suspended. A program of further research was then projected, aimed at reduction of operating costs. The result of this research was sinstallation of the only

eign producers. The practice has been to had been allow a preferential of at least 25 per-cent. With this as a stimulant, and with the Cuban-American development as an encourager, it is possible that the next include decade may witness the development of odd decade may witness the development of our domestic manganese industry able to our domestic beautiful description our domestic steel industry's needs for this material.

Manganese from Cuban ore pits, like the one at right, promises to solve a large part of the problem long surrounding this material which is essential in the manufacture of steel. By a flotation process developed by Americans—one step of which is shown below--these ores are supplying an increasing percentage of our needs for manganese vital in steel production. And without steel, nations would perish, especi wartime, from lack of guns, trucks, machinery, and other necessary equipment

"wet process sintering kiln" used in the Western hemisphere. Made with the help of F. L. Smdth & Co., Danish builders of metallurgical kilns. this mechanneal device "agglomerates" the wet concentrate, accumulating it in easilyhandled lumps or nodules. Development of the process was, for

Development of the process was foil all practical purposes, an American undertaking, since nearly all equipment for mine and concentrating plant was purchased from the United States, by American capital. American share reaped and will continue to reap the benefits in preacetime, and may find the development to be the salvation of its steel industry in time of war.

It is probably true that special local terral difficulties and special difficulties of transportation may proclude the possibility of applying to the ores of the United States the exact process used in Cuba. Nevertheless, it is possible that the Cuban development may serve as an important simulant in implementing the provisions of the recently-passed "stockpile" bill—a major purpose of which is to encourage development of our domestic sources.

This bill authorizes the expendature during the next four years—of \$100,000.000 to acquire stocks of stratege is a materials which are today obtained by the United States largely from abroad. It provides, furthermore, that all purchases shall be made in accordance with the "Buy-American" act of 1933, which states that the purchasing agent may allow a reasonable price preferential to domestic producers, as opposed to for-domestic producers, as opposed to for-

N evaluating the Cuban development. and its established and potential effect on the domestic economy of the United States, it should be remembered that manganese for steel is of course an essential ingredient of peace-time industrial operation. This is an age of steel in which we live. In the past half-century, the capacity of American steel furnaces has expanded over 1000 percent. Today, steel manufacturing is a \$4,200,000,000 industry, third largest in the nation, annually paying nearly a billion dollars in salaries and wages to over 600,000 employes And, just as steel has grown in importance, so manganese imports have increased, soaring from about 250,000 tons of ore in 1930 to over 900,000 tons in 1937

There is a growing universal awareness of the importance of all raw materials in preparedness planning. The effective power of a nation is no longer determined by the extent of its territory, nor by its wealth in gold, nor even by its strength in armies or equipment in munitions, but rather by its capacity for continuous production of hob-nailed boots and canned beans, tanks and rifles, ammunition and amplanes. It takes 17 men, manufacturing and distributing war materials, to keep one man on the fighting front. And for large scale industrialization, raw material is the first essential.

The implications of America's raw materials shortage were cogenity summed up recently by T. M. Girdler, chairman of Republic Steel Corporation, who said: "God grant that this country does not become moveded that the war, yet even if we are at peace while other nations are at war, our supplies of imported metals might be cut off for long periods. Down in Kentucky, buried in deep underground vaults, we have stored away a great pile of gold. The time might come when we would gladly give all of that gold for a pile of depended manganese..."

If another M.Day should dawn in America, Cuba will be ready with at least a partial solution to the crisis; the plant production can be stepped up beyond its present output. Or it may be that, when the emergency arrives, the United States will already have profited from the Cuban lesson in solving metallurgical difficulties now holding back development of manganese deposits in the United States proper.

all subsequent effort on the development of an altogether new system—the flotation method, which "washes" the ore free of impurities.

The method which was finally worked out and is used today at the Cuban-American plant, is a complex one. It involves grinding the ore to 'unlock' the manganese oxide from the gangue material; dilution (enormous quantities of water are used in the floatsion process); use of reagents for frothing and floating the manganese and for alimethod of the control of the con

Numerous mechanical difficulties were encountered from the beginning, but by February, 1935, the plant was on the

Eyes That See Through Atoms:

(In Two Parts-Part Two)

WHEN the spectroscopist burns a substance in an electric arc to force it to emit light, the molecules of which it is composed are torn asunder. These molecules consist, of course, merely of groups of atoms clinging together in definite patterns. When vitamins of hormones or other such company than the programes or other such company.

plex materials are studied, it is the molecules themselves which are of interest. rather than their constituent atoms. Though such materials would be destroyed if burned, fortunately they can be studied with the spectro scope by an entirely different method from the one used for detecting atomsa method which leaves them entirely undamaged. If a material is at all transparent, light can be sent through it, and waves of certain lengths will be absorbed by its molecules The spectrograph can then be used to obtain information about the molecules by analyzing, not the light which it receives, but that which is missing because absorbed before it enters the spectrograph

Wismin Au to absorbed with the control of the contr

the amount of light of wavelength 3280 angatroms which is absorbed by a layer of oil of measured thickness. Care must be taken to dissolve from the cod-liver oil any non-vitamun material which might absorb light waves of the same length, but such offending impurities can easily be clummated by mixing chemicals with the oil, which change them to some

ureasy again ringer, or A portion of a typical spectrogram as used to determine the Vitamin-A content of cod-liver oil. Reference figures at top and bottom indicate wavelengths in angstroms, while the tier of absorption spectra shows differences in light absorption for varying thicknesses of oil, as may be seen by doosting some prominent line or feature and running it downward.

absorbs is particularly convenient hecause the material is not destroyed, and the method is quick, clean, simple, and accurate. The two questions which any such analysis must answer are "What substances are present?" and "How much is there of each?" Light absorption measurements answer the second question very definitely. It is estimated that a layer of material only five atoms thick can, in many cases, be detected by the light it absorbs. By combining a microscope with a spectroscope speck of vanadium only 100 atoms long by 100 atoms brod by five atoms thick has, in microscope with a spectroscope a speck of vanadium only 100 atoms brod by five atoms thick has,

been observed Ability to detect such a clump of matter, containing only 50,000 atoms, weighing a billionth of a billionth as much as a dime, stamps this method as one of the most sensitive available.

ALL life ultimately de-pends on absorption of light, for it is the absorption of sunlight by the green leaves of plants which keeps the plant and animal worlds alive. Biologists have long used the spectroscope in their efforts to learn how the chlorophyll of green leaves manages to capture sunlight, and, with its aid, store in the leaf carbon from the air as cellulose, starch, and sugar. Many a leaf, green or brown or yellow, has been held before the slit of a spectrograph and had its inner structure plumbed with light in an effort to unravel the secrets of chlorophyll and carotin and other complex molecules on which life depends

In the ultra-short-wave region of the spectrum lies a broad band of waves entirely untouched except by the pioneering surveys of spectroscopists studying the

spectrum for its own sake. Such useful applications of these waves as there may be, and there are probably many, must wait until further experiments have been performed designed to perfect ways of handling these delicate rays. No one has yet succeeded in finding a solid material which is transparent to light waves borter than one fourth as long as those we call violet and longer than X rays, and which could be used for windows to allow light to enter and leave experimental apparatus. Thus far hydrogen and helium are the only materials which the oltra-short light waves

^{*} Copyright 1939, by the Author From the book "Atoms in Action The World of Creative Physics," by George Russell Harrison (Shortly to be published by William Morrow and Co.)

have been found able to penetrate, and though windows have been made of such tenuous gases, it is something of a trick to do this.

In the realm of the still shorter X rays-waves similar to light, but less than one thousandth as long-almost all matter becomes relatively transparent. Windows of many types are thus available, but the technic of handling X rave is still very crude; we have no lenses to bend them, no mirrors to reflect them, no microscopes to see with them. In spite of these lacks, two powerful methods of using X rays have been discovered. The first is to take ordinary shadow pictures with them, such as have revolutionized medicine and surgery during the past 40 years. The second is to send the X rays through a special type of spectrograph

Revealing as is the glimpse through flesh or metal which an X-ray shadow picture gives, it is crude compared with that obtained by means of a spectrograph. Then the glimpse is not the very atoms of matter themselves—even farther into the hearts of these atoms than is possible with an ordinary spectrograph.

IN 1912 Dr Max von Laue had the brilliant idea that a crystal, such as rocksalt or diamond, might separate X rays into beams of similar wavelength much as an ordinary diffraction grating separates light into its colors. The diffraction grating consists of thou-sands of parallel lines traced on a mirror: the crystal, argued you Lave. consists of millions of parallel lines of atoms, very close together, and perhaps these closely spaced lines are just what is needed to sort out the short-waved X rays. Experiments carried out at von Laue's suggestion showed that his idea was a good one. When a narrow beam of X rays was sent through a crystal, bright and dark spots appeared on a photographic film held behind the crystal, and the positions of these were found to depend on the different wavelengths in the X-ray beam, and on the arrangement of the atoms in the crystal. Sir William Bragg and Professor W. L. Bragg soon were able to arrange the crystal in a spectrograph so that clear, sharp, spectrum lines were obtained with X rays, entirely similar to those produced when visible or ultra-violet light is sent through an ordinary spectrograph.

If X rays are sent through a piece of metal, the small crystals of which it is composed can be studied with the X-ray spectrograph. This use of X rays has particular application in the heat trestment of steel. In one foundry it had drays been found necessary to keep certain metal parts for six hours in a furnace at high temperature, to bring them to the proper strength and hardness. Then the arrangement of crystals in the

The world's largest vacuum spectrograph, at the Massachusetts Institute of Tech-

nology. Since air is opaque to light waves shorter than about 2000 angstromall air must be pumped from the light source, the spectrograph, and the camera if such rays are to be photographed. Note vacuum pump and valve at rear

metal was studied, and the realmement of the atoms and crystals during heat treatment was followed with an X-ray spectrograph. As a result it became possible to work out theoretically a special short course of treatment lasting only half an hour, and on trial this proved to give better results than the longer treatment, at one fifth the cost.

Pieces of metal which undergo great stress, like anylane propellers, usually show changes in their internal structure a considerable time before they are ready to break. Propellers are almost always X rayed by the shadow method, to discover internal flaws, but they should also be studied from time to time with the X-ray spectroscope to insure that then atoms show no signs of wanting to let go of each other.

How well a piece of cloth will wear depends on the quality of the fibers of which it is woven, and how strong and flexibit these fibers will be depended of which they are composed. The X-ray spectrograph can be used to look right down through the fiber structure directly into the arrangement of atoms in these molecules, and sometimes shows that improved arrangements of atoms would make better molecules, hence sturder fibers, hence storquer of the property of

In cotton, wool, and asbestos fibers the melecules are found to consist of long strings of atoms lying side by side; here are substances respectively of vegetable, animal, and mineral origin which are similar in molecular and m outer form. Mica is composed of molecules which form broad flat crystalline plates arranged in layers which are held together so loosely that they can be split apart without difficulty. In diamond, on the other hand, carbon atoms hold

strongly to each other in three dimensions to form crystals which cannot be torn or split, and hence produce the hardest substance known. But change the arrangement of these diamond atoms ever so little and groups of them begin to slip apart, the crystal structure changes, and instead of the hard, abraave diamond, we have graphite, one of the softest and most slippery solids known.

If a piece of rubber is held between an X-ray tube and an X-ray pectrograph, the spectrum shows that so long as the rubber remains unstretched the molecules in tare arranged helter-skelter with no semblance of order-to-between the rubber is stretched, long chains of molecules appear, which contact and expand like coiled springs. The unusual ability of rubber to stretch and then return to its original shape can be traced directly to the molecules of which it is composed.

About lubrication the X-ray spectregraph gives important information, for it shows that greases and oils contain long molecules which slide over one another in layers.

The physiciat has been able to conribute the telephone, the radio, the motion picture, television, and a dozen other adjuncts of cavilization, only by using the powerful tools with which he has armed himself for the investigation of nature. Among these tools the spectrograph is outstanding, ever ready to yield new information on the structures of atoms, on the arrangements of the molecules which these atoms form, on the multitudes of substances which can be produced from these molecules, and hence on many of the activities of men, machines, and material university.

Two Elements For One

THE Fifth Washington Conference on Theoretical Physics was sitting in solemn conclave when the news broke. Professor Nils Bohr of Princeton and Professor Enrico Fermi of Columbia rose to open the meeting with an account of some research going on in a Berlin laboratory

Professors Bohr and Fermi are Nobel Prize winners both, and their names are as well known to scientists as Toscaninni's is to music lovers. The Conference therefore expected something extra special. They weren't disappointed.

It was January 26, 1939. A few weeks before, at the Kaiser Wilhelm Institute in Berlin, Dr. Otto Hahn, a distinguished German physicsh, had obtained an ut-terly unexpected result from some more less routine experiments. Following the original example of Professor Fern. Dr. Hahn and his co-worker. F Strassmann, had for many months been bombarding uranium with neutrons and studying the debris left by this atomic designs the debris left by this atomic was a constant of the control of

It would not have surprised them at all to find radium as one of the products. In fact, they had done so before, or thought they had Radium and uranium are near neighbors in the table of elements, and it is nothing new for scientists to transform one element into another close to it in weight and electric charge.

But it was news, and big news, to discover barium among the debris barium, which is only a little more than half as heavy as uranium. If meant that the neitron bullets had succeeded not merely in knocking a few chips off the old block, but in blowing the whole atom asunder with a terrific explosion.

The theoretical and a state of the control of the c

A few insiders had already jumped the gun shead of the Conference and of the rest who learned of the discovery through the newspapers. In Copenhagen, Dr. O. R. Frisch and Professor Lise Meitner, who had previously worked with Hahn on the same problem, had verified his results ten days earlier. A group of Columbia University physicists, including Fermi, independently thought up and carried out a similar experiment

The Most Important Scientific Discovery of the Present Year is also the Biggest Explosion in Atomic History... Splitting the Uranium Atom

By JEAN HARRINGTON

by January 25, the day before the Conference. By the time the meeting wound up its affairs January 28. three more laboratories—at the Carnege Institution of Washington, Johns Hopkins, and the University of California—joined the horus of confirmation. In a word, Hahn was right. Uranium, and thorum, too (thorum is also among the heavest elements), had been split in two by neutron hombardment

THE phenomenon was quickly dubbed "nuclear fassion," and in the months ensuing since its discovery, nuclear fission has grabbed the spotlight from the "heavy electron" sensation of 1937-8 Dozens of the world's top-flight physicists have been busy as bees, roaming the clover of a new field of research.

The first task of the investigators was to get a picture of what had happened. Dr. Frisch and Miss Meitner promptly supplied a pretty good one.

The nucleus of an element, they pointed out, is now thought of as an aggregation of protons and neutrons packed together into an isonocievably small space. The number of protons, or units of positive electric charge, accounts for the chemical behavior of the element. Neutrons are units of weight and have no charge. Together the neutrons and protons make up the mass of the nucleus.

The simplest nucleus is the single proton belonging to the lightest element, hydrogen. Going up the atomic scale, adding one proton and a varying number of neutrons for each successive element, we arrive at last at uranium. This heaviest of elements is invariably characterized by its 92 protons; in its commonest form it contains 146 neutrons as well, giving it a total weight of 238. Two other forms, weighing 235 and 234. also occur in small quantities. These are called the three natural isotopes of uranium, and are distinguished by the shorthand symbols U238, U238, and U234 Now all the known elements heavier

Now all the known elements heavier than mercury—that is, thallium, lead, bismuth, polonium, radon, radium, actinium, thorium, protactinium, and uranium—have isotopes that are naturally radioactive. Their nuclei are so complicated that occasionally one will spontaneously simplify itself by shooting off a particle.

We can picture the process nicely if we imagine for a moment that the radioactive nucleus is like a drop of water, composed of many molecules. One of the molecules near the surface somehow acquires a little more energy than its fellows and evaporates.

The stage is now set to return to Dr. Frisch and Miss Meitner, whom we left some paragraphs ago. Their conception of the nuclear fassion process continues the analogy of the drop of water. Suppose the H₂O molecules are volently agutated by a source of energy outside the drop. Instead of evaporating gradually, the drop splits in two. Similarly, a uranium nucleus, stimulated by the Impact of a neutron bullet, may divide into we smaller nuclei of roughly equal size.

These fragments are in themselves unstable, and quickly disantegrate to form still other nuclei. In fact, a whole series of transmutations generally follows the fission of uranium or thorium. Since Hahn first found barium among the products, he and other investigators have identified antimony, tellurium, codine, xenon, caesium, and lanthanum in one group; bromine, krypton, rub-dium, strontium, and yttrium in another.

with many possible additions. The explanation is simple enough. The original fragments contain too many neutrons in relation to their proton content, and must get rid of them to achieve a stable form. One of two things happens. The nucleus may simply expel a whole neutron, reducing its weight by a unit. Or one of the neutrons may be converted into a proton plus a negative electron inside the nucleus, which promptly ejects the electron. In the latter case, the nucleus remains approximately the same weight but acquires an additional positive charge. thus becoming a chemically different element. Experiments have proved that both these types of disintegration actually do take place.

No one knows yet whether the same two original products are always formed when uranium divides, or what they are. But if one of the fragments is barium, with 56 protons, the other must have 92 minus 56, or 36, protons, which would make it an isotope of the gas krypton.

If the barium tries to stabilize itself by emitting an electron, it becomes a lanthanum isotope, which may in turn convert itself into cerium by electron emission. The krypton also disintegrates in the same way, successively be-

coming rubidium, strontium, and perhaps yttrium and zirconium. We can show these chain reactions by a formula where the subscripts represent the number of protons of the prod-

$$Ba_{56} \rightarrow La_{57} \rightarrow Ce_{58}$$

 $Kr_{36} \rightarrow Rb_{57} \rightarrow Sr_{38} \rightarrow$

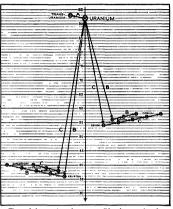

Y₃₀ → Zr₄₀.
Again, if the two original fragments are strontium and xenon instead of barium and krypton, we may have the following chain reactions:

$$\begin{array}{l} \operatorname{Sr}_{88} \to \operatorname{Y}_{89} \to \operatorname{Zr}_{40} \\ \operatorname{Xe}_{84} \to \operatorname{Cs}_{88} \to \operatorname{Ba}_{86} \to \operatorname{La}_{87} \\ \to \operatorname{Ce}_{88} \end{array}$$

In a discovery like this in the realm of pure science, it is always easier to see the theoretical importance than to find a practical application. The fission of uranium has provided a field day for the physicists who like to take atoms apart and find out what makes them tick. It adds a new chapter to their knowledge of the nucleus-the forces that hold it together, the collective behavior of its constituent parts, its reaction "under fire," its des-

In addition, it clears up a mystery of long standing, dealing with elements beavier than ursunum. When, in 1934. Fermi began his experiments with uranium, he soon found that negative electrons vere always emitted under neutron bombardment. We know now that they are usually the products of the chan reactions just described; but at that time nuclear fassion was not even dreamed of. Fermi naturally concluded that the uranium nucleus captured the neutron, converted it into a proton, and excelled an electron.

Here, then, was a supposedly new element with 59 protons, unknown to nature. Moreover, this new element seemed to emit another electron to form another new neucleus of 94 protons. These were called "transurante" elements, and up until lately they were a headache to the numerous investigators who worked on them. The latter kept finding more and more transurante; and when they studied their chemical properties they found inexplicable variations. Last No-womber, just a few weeks before Dr. Hahn stumbled on the real secret, he announced that he had found at least 16 different kinds of nuclei resulting from neutron bombardment of uranium. Some of them, indeed, behaved chemically like barium, lanthamum, and other light elements, but they were thought to be isometically the sound of the sound of

Three of the reactions that are possible when uranium is bombarded by neutrons. Each horisontal line represents a chemical element containing the indicated number of protons, A represents the formation of transuranium. B shows the split of uranium into barium and krypton, with the chair reaction that follows it. C represents the division into zenon and strontium followed by its own subsequent chair reaction

topes or isomers of heavier elements such as radium. (Isomers are nuclei having the same total weight but different chemical properties. Isotopes have the same proton content but varying total weights.)

When the announcement of nuclear fission came, it was immediately realized that the electrons were not in general emitted by the uranum nucleus itself but by its lighter fragments. The mystery of "transuranic ciements" was practically solved. It does seem, however, that a neutron bullet occasionally fails to give its target quite enough energy to divide; the uranium isotope disintegrates by electron emission and really does form a new element with 93 protons. But one such

So much for the theoretical significance of nuclear fission, far-reaching though it is. It is pretty hard to amass as much weight on the practical side of the balance. But our imaginations are immediately seized by the terrific amount of energy liberated when a single uranum nucleus explodes. The two fragments fly apart activated by some 200,000,000 electron volts—a total far greater than that associated with any other atomic phenomenon except cosmic rave.

The tabloids love to write of blowing

up the world with a gram of matter, and u's not such a sensational idea as one might think. Even a tiny mass has an enormous potential of energy if it could but be freed. It is just such a conversion of mass into energy that speeds the fission fragments on their way.

The weight of any nucleus is mer quite equal to the sum of its individual protons and neutrons. A small proportion of their mass, called the "packing fraction" or "mass defect." as somehow transformed into the force that holds the nucleus together. Otherwise the positively charged protons would all repel each other and scatter in every direction.

The packing fraction for uranium is, because of its large number of particles, greater than that for the simpler elements into which it divides. This difference in energy is released with the two fission fragments.

OF course, 200,000,000 volts is an astounding energy compared with the size of the bodies which possess it. But for practical

purposes it is absurdly small, amounting only to about three ten thousandths of an erg. In more everyday terms, it would take 25,000 billion fassions per second to produce one horsepower—figures which dwarf even the national budget. The very best a laboratory can do so far is produce a few hundreds per second.

If atom smashing could be made more efficient, power production by means of nuclear fission would not be beyond the realms of possibility. But under present conditions, the process is as inefficient as removing the sand from a beach a grain at a time. Or, more graphically, it is like shooting with buckshot at a netwood of beads strung yards apart. The size of the target is comparable with the size of the projectile, the empty space between targets is enormous compared with the diameter of either, the stream of bullets cannot be well controlled or aimed, and therefore it is much more probable that a neutron projectile will fly past a uranium nucleus than to score a direct hit and be captured. In fact the chances are thousands to one against fission taking place.

Neutrons have proved themselves more efficient atom-busters, however, than other projectiles like protons or alpha particles, which are positively charged and hence repelled by the positive nuclei. To get a stream of neutrons, a preliminary bombardment must take place. One common method employs the radioactive gas radon, which spontaneously emits alpha particles (helium nuclei with double charge and mass four). The alpha particles are allowed to fall on a sheet of beryllium, where they join with the beryllium nuclei to form carbon plus neutrons. The reaction is shown by the formula.

 $Be_4^0 + He_2^4 \rightarrow C_6^{13} \rightarrow C_6^{12} + n_0^1$ where the superscripts are the atomic

weights and the subscripts the charge.

The stream of positive particles from the cyclotron may also be used to bombard beryllium and thus produce neutrons. The high energy and great number of cyclotron particles make them more efficient neutron makers than the natural radio-alba particles

Once created, the neutron beam is air rected against a uranium target. The products are studied in various ways, if the investigators want to find the energy of the fragments, the target is placed in an ionization chamber, falled with a gas at low pressure. The fragments rip through the gas atoms, disrupting their outer electron structure to form ions. The gas sions are drawn to a wire where they constitute a tiny electric current, and the magnitude of this current gives a clue to the energy of the fission products.

If the experimenters want the range of the particles—that is, the distance they travel before their kinetic energy is all used up—they may choose a Wilson cloud chamber which automatically photographs the track of ions the nucleus leaves behind it.

If they want to know the number of fissions occurring in a given time, they have an electric counter at their command, based on the same principle as the ionization chamber. A modification of the same instrument is used to look for electrons or neutrons emitted in the fission process or in the chain reactions that follow.

The problem of identifying the products as aomewhat different one, and is complicated by the large number of elements which may be formed. Here the debrts is collected on a sheet of Cellophane or paper placed close to the uranum target. Each variety of isotope on the sheet has a definite rate of disnitegration—it may be anywhere from a fraction of a second to several days—and this time is characteristic of the element to which the isotope belongs.

To measure this period of decay, the collecting paper is placed near an electric counter. If the activity of one product decays to half its original value in 87 minutes, for example, that product is immediately known as an stope of barium, Ba 127, which is known from other experiments to have a characteristic "half life" of 87 minutes. The driftelly of this method of identification is, of course, in separating the half-lives when two or more elements are decaying

Stereoscopic cloud chamber photograph showing tracks of two heavy fragments recoiling in opposite d ons from a uranium nucleus recti struck by a neutron. The uranium is on a collection film (one of the broad, bright borzzontal lines). The fragment tracks are fainter and nearly vertical. The fork near the lower end of the track resulted from a collision of one fragment with a gas atom in the cloud chamber. The double picture is obtained by photographing the chamber simultaneously from two points of view, to get three-dimensional perspective. Photographed by Corson and Thornton at the University of California

together, and also in classifying a halflife belonging to an isotope previously unknown.

Another method of studying the products is to perform the experiment under water, then analyze the water chemically. Suppose we suspect that a few nuclei of radioactive lanthanum are present. This is too small a quantity to separate directly. But if a larger amount a stable lanthanum compound is added to the water, both stable and unstable lanthanum atoms can be precipitated out. If this precipitate is then shown to be radioactive, we have proved our suspicion was correct. Similarly the water can be tested for radioactive barium by adding a stable barium compound, and so on.

STILL a third attack on the problem of identification has been made by Philip Abelson at the University of Galifornia. He had been studying the natural X rays from the supposed "transurance elements"; and put on the right track by the discovery of unclear fission, he quickly showed that these X rays had

wavelengths characteristic of iodine and

Research along all these lines is proceeding at breakneck speed. Experiments similar to those with uranium have been performed on thorium (7h ½) with similar results, except that only fast neutrons are effective in splitting the thorium nucleus, while both fast and slow work well on uranum. Other heavy elements, such as gold and tungsten, show some slight tendency to underge fission

Fermi and others have been trying to determine which of the three uranum sotopes are involved, and how the process is related to the speed of the neutron projectiles. Duke University scientists are investigating gamma radiations connected with fission, and the University of California is piling up data in all branches of the research. Bohr at Primeton, Solomon in Paris, and many another are concerning themselves chiefly with theory.

Irêne Cure and P. Savitch, who were responsible for much of the ground work enabling Hahn to identify the products of his fission experiments, have been carrying on the classification work in Paris. Johot, as well as groups of physcients at Columbia, the Carnege Institution, and Cambridge University, have concentrated on the study of secondary neutrons emitted at the moment of fission and in later reactions

The latter problem brings up an interesting and rather disturbing aspect of the case. These secondary neutrons constitute a fresh supply of "bullets" to produce new fissions. Thus we are faced with a vicious circle, with one explosion setting off another, and energy being continuously and cumulatively released. It is probable that a sufficiently large mass of uranium would be explosive if its atoms once got well started dividing. As a matter of fact, the scientists are pretty nervous over the dangerous forces they are unleashing, and are hurriedly devising means to control them.

It may or may not be significant that, since early spring, no accounts of research on nuclear fission have been heard from Germany—not even from discoverer Hahn. It is not unlikely that the German government, spotting a potentially powerful weapon of war, has innecessible to the second state of the posed military secrecy on all recent German investigations. A large concentration of isotope 255, subjected to neutron bombardment, might conceivably blow up all London or Paris.

It has been impossible, even in this long article, to mention all the thousand aspects of this fascinating phenomenon. or name many of the able contributors to the sum of information amassed since last January. But the fact remains that unclear fassion is the most important scientific discovery of the year, and holds who knows what promise for the future.

PRESERVED IN PLASTICS

TWO methods of preserving indisnitely in their natural colors such aggregatural specimens as leaves flowers and the specimens as leaves to be a such as the specimens of the specimens of the United States Department of Agriculture. The presences, while supplementing each other, have different fields of application—one for deal and the other for fresh muteral.

In the method studied by Dr. Charles E. Sando, specimens are suspended and embedded in methacrylate, a crystalclear plastic. In this process, the specimens must be dehydrated to prevent moisture from clouding the glass-like plastic material. They may be an dried or dehydrated by use of alcohol or ether

Grains or seeds, insects, or anything that does not lose its color or shape with drying, may be preserved by this method. Once the plastic sets, it can be machined and polished so that the specimen may be viewed from any angle without distortion.

Modern plastics are used to do to the intent what the resins that turned into amber did by accident millenia ago—to preserve insects and plant products in full color and natural form. At left and right are specimens embedded in clear plastic

In the second method, sperimens are not immersed in plastics but are treated to toughen tissues and set the natural color. At right a spray of peach blossom is lifted from water-removing syrup after being refrigerated the proper number of days. It will then be placed temporarily between streets of this redules account of the color of the results of the color of the results of th

The other method, developed by G. R. Fescanden, is a chemical process for treating fresh plant material in such a way as to toughen the tissues and set the natural color. The natural beauty of flowers, or the exact appearance of either healthy or diseased leaves, can be preserved by immersion in specially formulated water-memoning syrups. Each plant species requires an individual treatment which has to be worked out from seven general types of formulas Specimens preserved by this new

The curing completed, the specimen loses its temporary film covering and is mounted on a glass plate in a water-resistant, resinuous compound. A cellulose acetate film (at right) is then placed over it or protection. It is finally added to the collection (at added to the collection (at added to the collection) (at the collec

method are sealed between sheets of cellulose film.

Due to the expected permanence of specimens preserved by either method, excellent records of both healthy and abnormal plants and insects may be made available for research and study.

Although numerous specimens have been prepared by both methods, there are a number of difficulties to be overcome before the final methods can be released for general use.

High Blood Pressure

WHEN Sir Marc Armand Ruffer made his medical study of ancient nummines found in Nubis he reported that many of these worthies had suffered from hardening of the arteries. Dr. R. H. Hoffman, commenting on this his "Struggle for Health," as ali t was natural to assume that the ancient Nubians had high blood pressure.

Supposed beserved, they did not smoke. Supposed beserved, they did not drink hard liquous supposed beserved, they did not drink hard liquous supposed beserved. The work of the little read is the supposed by the little read in the little read

In the Archives of Internal Medicane for July, 1930, you will find an interesting study by Drs. Walter C. Alvares and L. I. Stanley of 6000 princeners and 400 prison guards. The guards had duly resource than the prisoners. The prisoners were both more calm and less obese than the guards. Possibly nervous excitement entered the picture here. The guards' blood pressure was taken when they came to apply for the hope to the prisoners, unworried and calm, would tend to have lower blood pressure.

It was found also that the bloodpressure level did not rise with age. It was affected little if any by habits of dissipation, by the use of tobacco, alcohol, or drugs, or by venereal infection. Cool weather slightly raised the blood pressure abent high blood pressure appeared to be a matter of heredity and "nerres." Even the impassive Chinese usually develops higher blood pressure when he comes to buttling America.

BUT what is "high" blood pressure? What might be high for me might, all things considered, be normal for you. In 1928 Dr. Herman O. Mosenthal delared it was quite difficult to distinguish between normal and high blood pressure by making a single test. The patient must rest and be under close observation for some time.

There are several types of high blood pressure (hypertension) too, some mild and almost harmless, others not so harmless. Patients with a benign type of the ill return to normal blood pressure after a little rest.

Dr. Mosenthal, mentioned above, also tells of curing one woman's high blood pressure (at least for the time) by preVarious are the Possible Causes of this Ill, but Worry and Nervous Excitement Probably are Large Factors...Calm Rest the Best Cure...Loaf, Loaf, Loaf

By T. SWANN HARDING

scribing freedom from community committee work. This was after she had unsuccessfully taken two sanitarium rest cures and a prolonged trip South, and

had had a major surgical operation
The relationship that should exist between blood pressure and age, contrary
to much lay opinion, remains unsettled.
Dr. Temple Gray told the British Hunterian Society in 1929 that the expres-

Apprehension when the blood pressure is taken may actually cause the pressure to rise abnormally

sion, "A man is as old as his arteries," had done more harm than any other medical statement. He said some people attain advanced age with their arteries in seemingly hopeless condition; others die young with apparently healthy arteries. He claimed to have seen persons in apparent health with extremely high blood pressures. Other doctors say women can withstand such hypertension well but never men.

Some physicians speak of a "lowblood-pressure type." It consists of artistic persons who suffer from lassitude and an inability to do intellectual work. They come to doctors much earlier than the high-blood-pressure type.

Others speak of racial high blood pressure and admonish us to adopt a vegetarian diet because the Chinese and the East Indians have low blood pressures. But the Eskimos also have relatively low blood pressure and no undue affliction with kidney trouble, yet they eat only meat. What part does diet play

in producing high blood pressure?

Dr. Mosenthal and his associates reported upon extensive studies of applicants for insurance in The Journal bith American Medical Association for April 3, 1937. They wrote: "People with hypertension do not habitually eat more protein or more salt than normal persons. There is no evidence to show that a low protein diet followed by a hypertensive patient, will materially reduce the blood pressure provided there is no amemia."

WOMEN, it was found, tend to adopt the diets containing much less protein than those the men eat, but blood pressures do not follow this trend. Neither the salt nor the fluid intake affect the blood pressure. Alvare: has shown in his studies also that, though women are as a whole more prone to constipation than men, men have higher blood pressure. In general, constipation and low blood pressure go together.

There is, then, no average normal blood pressure for persons of a certain age or weight. Each individual must be considered as an individual. The question is: Is this specific blood pressure high for this particular individual at this time?

In an editorial review for the Journal of Nutrition, in July, 1932, Dr. Fritz Bischoff pretty thoroughly showed that there is no evidence that diet has anything directly to do with kidney and blood vessel changes. Why, then, do high-blood-pressure sufferers go on diets? Thirty-odd years ago, when high blood pressure was discovered, it was thought to be due to the kidney disease called nephritis and to the loss of elasticity in the arterial walls called arteriosclerosis. These ideas continue to hang over, though it is now known that primary kidney disease is rare and arterial hardening usually moderate. The dietary restrictions came in with these old ideas. Time has proved most of them to be silly and unnecessary. Even restrictions against exercise have been removed, provided the exercise be in moderation. Above all, the sufferers must avoid stress and strain, for it has repeatedly been shown that, in some, a little rest lowers blood pressures almost miraculously.

Salt is often denied high-blood-pres sure sufferers, perhaps for insufficient reason. The best medical authorities now agree that, within ordinary limitations, the salt intake does not affect blood pressure. Prolonged investigation of 11 patients was published in Archives of Internal Medicine for October, 1929, for example. Sometimes these people got as much as an ounce of salt a day, sometimes only a fifteenth of an ounce or so. This was done after an initial period of rest in bed on a good diet for from ten days to two weeks. Occasionally salt was injected into the veins of the subjects in considerable quantity, but their blood pressures remained unaffected.

Low-protein diets came in with the theory that kidney disease and high blood pressure were related. Today, the very assumption that long-continued excretion of the digestive end-products of excess meat consumed will irreparably injure the kidneys, is questioned More over, even sufferers from degenerative kidney disease must have a minimum of protein or they will start to digest their own tissues. If high blood pressure is uncomplicated by such kidney degeneration the meat tabu seems unwarranted The diet has been proved to have very little to do with directly causing kidney, heart, and blood-vessel ailments.

WHAT about other conditions assotion to the popular mind with high blood pressure? Constipation often accompanies low blood pressure. Obesity tends to promote high blood pressure and is bad for its sufferers.

The death rate of those who suffer from high blood pressure in acute forms is very high. These deaths occur from three general causes, heart failure or cerebral degeneration being commonest, some form of kidney failure more rare However, the death rate of those with only moderately high blood pressure is about that of normals.

There is a tendency for nervous people and neurotics to have hypertension. Acute infections and intestinal auto-intoxication—assuming the latter exists, which those who appear to know most now deny—do not seem to increase the blood pressure.

Thus, in The Journal of the American Medical Association, September 20, 1990, we find a doctor claiming to have gotten excellent results on 200 patients by using biamuth subnitrate. But in the same journal for February 13, 1932, Dr. David Ayman reported his complete in-ability to get positive results by pre-scribing this drug for from three to nine mouths in treating 18 high-blood-presembles.

Traditionally, metropolitan life with the strenuous excitement of its stock exchanges and intensive life conduces to high blood pressure but a comparable degree of nervous tension can be and often is developed (for reason) on the farm

sure patients. Indeed, Dr. Ayman began to think that this drug and perhaps all others used in high blood pressure had only the effect of suggestion. In spite of the treatment used, the investigator always claimed to produce partial or complete relief from the annoying symptoms of high blood pressure. Moderate or marked drop in the pressure was always asid to follow. Yet the symptomatic relief was often out of all proportion to the fall in blood pressure, while the blood pressure often fell without the blood pressure often fell without

relief of the patient's symptoms. The various investigators had used a wide variety of rest cures, low-salt diets. low-protein diets, and regimens, as well as treatments with heat, the application of radium to the skull, watermelon extract, and all standard drugs used in hypertension. Complete failure was seldom or never reported. Yet there was no cure for high blood pressure! So Dr. Avman decided to try on 40 unselected sufferers from high blood pressure a treatment that he was sure could not only not aid them but would lack all effect He used a few drops of dilute hydrochloric acid in water. This at least tasted like a drug and it was enthusiastically recommended when given. The results were miraculous. There was definite improvement in symptoms in 32 or 33 cases! Dr. Ayman wrote: "The symptoms associated with uncomplicated essential hypertension may frequently be relieved by the suggestion inherent in any seriously and enthusiastically prescribed drug or method of therapy. This is the probable explanation of many successes reported in the

past."

Dr. Ayman also found that two weeks' rest abed worked wonders. He found wide variations in the blood pressure taking place without any effort to treat it at all. Obviously, relaxation was most beneficial. as Dr. Mosenthal said in 1928

and as Dr. Arthur S. Grainger told the American Medical Association in July, 1929.

A year or so ago, Dr. H. C. Gram. of Denmark, tried all the most commonly recommended drugs or regimens for hypertension. He found that rest in bed and freedom from worry did more than all else. If the patient was dieted, then the diet got the credit. If the patient was drugged, the drug got the credit rest should have had. If the patient was simply rested, the results were usually as beneficial. Hence the fall of blood pressure under medical care seemed often half-mythical. The first measurement of the blood pressure also is an alarming event calculated to run it up. Hence the gradual fall after "treatment" is often natural but is credited to the treatment

THE best treatment probably involves telleving the conditions in the environment that aggravate a rise in blood pressure. This means: Seek to displace an excitable and to adopt a calm attitude. De all things in moderation. Limit social obligations. Stop worrying, Remember that spontaneous remissions often occur, that no diet is proved beneficial, that some sufferers resist every recommended regimen. No drug cutres, the nece take no patent medicines or drug remedies for high blood pressure. Seek the care of a competent physician.

It is not wise for every sufferer to try arbitrarily to reduce his blood pressure to an assumed normal. High blood pressure is often a benign, compensatory mechanism. One has to learn to abide it. Each patient can be assisted by his doctor to attain an individual comfort level suited to his needs.

High blood pressure has been called the disease of American life, so cultivate the spirit of leisure, loaf more, dream

Conducted by F. D. Mc HUGH

TO DETERMINE MOISTURE CONTENT OF GASES

MOISTURE is an clusive agent—alldetect, difficult to eliminate or control. When there is moisture in supposedly dry annealing gases, high-carbon steel decarburizzes and becomes unsatisfactory for

Dew point, and hence moisture content, of gas being read directly

many uses. Razor blades made from it have poor edges; automobile and sirplane gears do not hold up in service

To help eliminate this handicap, General Electric engineers have devised a convenient, portable dew-point potentiometer for determining the moisture content of gases. This is done by measuring the "dew point," or temperature at which moisture will condense from a sample of the gas

A small stream of the gas is conducted through a compartment of the instrument. The mosture condenses on a thin, metallic mirrow which is connected to a thermocouple and then to an indicating instrument. An operator regulates the flow of a cooling medium, usually carbon dioxide, until alight disputations and condensation of mosture on adjustments will cause the alternate evaporation and condensation of mosture or the control of this point, the despoint the instrument by balancing the galvanometer by turning a kind of the control of the cont

The instrument is expected to prove of special value in steel mills for measuring the moisture content of annealing gases;

also in chemical plants, gas plants, industrial and research laboratories, and in shop tests generally where the moisture content of gases must be known for testing or control purposes. The device weight 16 pounds and is carried in a case 14½ inches long, 8½ inches wide, and 6½ inches high.

RING GEARS CAST

EXPERIMENTAL work in casting gear hounced by the Ford Motor Company just over a year ago, has been wholly successful, and centrifugally-cast gears now are in regular production

Greater strength, lighter weight, and faster production are the principal advantages of the gears made by the new method, according to R. H. McCarroll, Ford metallurgist. By using sand cores in the die, undercuts can be made which would be impossible in a conventional forging, and

this saves weight and metal Still more important, however, is the greater strength of these gears made by centrifugal casting. Eiched sections show the reason I some forgings, these of metal flow are parallel to lines of greatest stress. Because of absence of all flow lines in the centrifugal castings, this condition does not exist. The metal is equally strong in all directions.

The samplicity of the centrifugal method is especially notworthy. The flow, which are made of a special low carbon steel, are mounted in units of 18 on a turntable Each die begins to spin as it approaches the two munutes required for the metal to two munutes required for the metal to solidify, and then stops turning in time for the operator to remove the hot blank and prepare the fee for the next casting

SEALING PLATINUM TO PYREX

A SATISFACTORY wal between platinum and Pyrex glass, for use in the construction of chemical and other scientific apparatus, has been developed by Edward Wichers and C. P. Saylor of the Chemistry Division of the Bureau of Standards

The general problem of joining metals and glasses has been studied by many investigators, but the fact that the thermal expansions of platinum and glass are so different has always caused trouble. Thus, when a platinum wire or rod is coated

Turntable on which gears are centrifugally cast in 18 dies

with hot glass, subsequent cooling will crack the glass or pull 11 loose from the metal. The difficulty has been surmounted by using a seamless tube of platinum instead of a wire or rod. If the walls of the tube are thin as compared with its length (a ratio of about 1 to 12), the shrinkage forces are not great enough to crack the glass in-

of about 1 to 12), the strumsage sources in not great enough to crack the glass in-ternally or to pull the metal away from it. The mechanical principles governing the platinum-Pyrex seals can also be applied to other metal-glass seals of the tubular type. They are simple to construct, and do not require any unusual apparatus or extraordinary skill in glass blown; in glass of the platin to the platin the glass of the g

GAS MASK FOR

OXYGEN INHALATION

An invention which promises great adulty to swe lives and revore health to suffering patients recently was demon strated by a group of Mayo Clinic plays came at a meeting of the American Med call Association. It is a new gas musk for giving oxygen efficiently and economically one of the famous Mayo brothers, the last Dr. C. W. Mayo, and its inventors, Drs. Walter M. Boulobly, W. R. Lowdicke II, and A. H. Bulbulian, described its promising medical uses to the assembled decires.

One patient, desperately ill with rheumatic heart disease, began to improve immediately when he was given 100 percent oxygen with the new apparatus, although he had been expected to die. The treatment was not a cure, but an aid to the patient's fahl to recover.

Patients suffering with gas gangrene and tetanus or lockjaw have been helped to recovery by oxygen given with this new type of mask. The recovery in these cases is due to the fact that both of these ailmosts are caused by germs of the kind that cannot hive in an atmosphere that contains oxygen

The mask is also being used to give oxy gen to patients in shock or collapse following injury or surgical operation, in cases of abdominal distension, for headaches fol-

lowing air injections into the brain for diagnosis of brain tumors, for migraine, and for a number of lung disorders. The mask has also been installed on an airline for use of pilots and passengers threatened by oxygen-lack at high altitudes.

The reason the new apparatus is finding such a wide field of usefulness is because it can be used in the patient's home as well as in large, well-equipped hospitals and because it reduces enormously the cost of oxy-

Patients suffering from many types of diseases an er eleved by inhalation of oxygen, or an oxygenhelium mixture as shown above, through a newly developed mask. In the drawing at the left, note that the mask covers only the nose, leaving the lips of the patient free

gen treatment. The cost of giving oxygen by oxygen tents, the method used before invention of the new mask, is from \$21 to \$25 a day. This has prevented the use of oxygen except in very few cases, chelly severely ill pneumonia patients. With the new apparatus the cost of the oxygen should average only \$5 to \$8 a day, Dr Boothby

stated. The reduction in price, made possible by the efficiency of the apparatus, will enable doctors to use helium quite generally in the treatment of asthma. Until relatively recently, Dr. Boothby pointed out, helium was never used except for the most severe asthma cases, because of the high cost. With the new apparatus, both helium and orygen can be used, starting with a mixture of oxy.

gen and helium and, as the patient gets better, increasing the proportion of the less expensive oxygen till the patient is getting all oxygen—Science Service

BLACK ELECTROPLATING

DEEP black deposits, suitable for automobile hardware, business machines, flashlight cases, and the like, may now be applied by electroplating, according to De Pout chemists. The solution used con tama ammonium mobilatic, nickel sulfate, offers attractive possibilities, being superior to black mixed plating and other similar black counting processes.

REMEMBER 'EM'

THERE have been more than 4000 makes of automobiles since the first car propelled by an internal combustion engine appeared in France in 1868!

HIGHER VITAMIN CONTENT IN WHITE BREAD

A LOAF of white bread which has the untamin-B, content of a whole-wheat loaf, some five times as much as ordinary white bread, was predicted to the Massachusetts Institute of Technology food conference recently by Charles Frey, Alfred Schultz, and Lawrence Atkin, all of the Fleischmann Laboratories.

Vitamin B., or thasmin, is an important factor in nutrition but it is not stored in the body to any significant extent and thus must be contained in basic foods. Cereal products, maintay of the national diet, are suitable for this but these products, especially bread, have been increasingly deprived of their natural vitamin content in recent years.

The problem of restoring this loss, sometimes as great as 93 percent, has been tried along many lines, but the latest

A Douglas DC4 in flight

and most practical employs a new yeast. This yeast contains enough thanim to produce a loaf of white bread with the vitamin to produce a loaf of white bread with the vitamin content of a whole wheat load that without any loss of palatableness. Although made by a new process, the yeast offers no new technical problems ance its baking proposed of such a loaf at a low root-increase would be a boon to low-income groups, it is de-clared—Science Seriese.

ACTION OF LATEX ON POLISHED ALUMINUM

FilkMS of rubber, applied in the form of lates, are sometimes used as a means of protecting the polluhed surfaces of metallic mirrors and sumilar articles from scratches and dust while in storage and during ship meni. When ordinary commercial lates is applied to polished aluminum, however, a bluish discoloration is produced which re-

mains when the film of rubber a strapped of Tests made at the National Bureau of Standards indicated that the discoloration was produced, not by the rubber, but by ammonia which is almost universally employed as a preservative for latex. When the ammonia is removed, latex no longer discolors alumnum. Ammonia-free latex preserved by the addition of the requisite without action on alumnum.

A FLEET OF DC-4's

OUITE recently the writer had the pleasure of visiting the new Douglas DC-4 at Newark Airport. No matter how blase one may be, the new airliner gives one a thrill by its size, its superlative finish, and its innumerable modern devices and accessories. It is not at all surprising to learn that W. A. Patterson, President of United Air Lines, has decided to purchase a fleet of six of the new DC-4's, at a cost of \$500,000 each, for use in transcontinental sleeper traffic The decision to purchase six ships was based on a careful estimate of the number of airplanes required to maintain adequate coast-to-coast aleeper service Analysis of the airline itself, backed by the estimates of independent market research groups, showed definitely that there would be sufficient traffic to warrant this bold move This year, for example, transcontinental business is running 32 percent ahead of last year's business.

While we have reported the DC-4 already in these columns, it is interesting to present the final specifications in brief, with the changes which the airline has asked for and obtained.

The passenger cabin is supercharged to a pressure equivalent to that of 8000 feet above sea-level when the plane is actually flying at 15,000 feet altitude. The produc tion type airplane will have a gross weight of 66,500 pounds Maximum speed will be 237 miles per hour; cruising speed using 74 percent of rated power, will be 210 miles per hour Range at 191 miles per hour, with 42 passengers and 3000 pounds of mail, will be 1425 miles or approximately one half the air distance across the United The eight fuel tanks will carry States 2050 gallons of gasoline Wing span will be 138 feet 3 inches, and overall length will be 97 feet 7 inches.

Cabin accommodations will be liberal. The floor-to-ceiling distance will be 7 1/2 feet and the inside width more than 10 feet. As a day plane, the DC4 will have accommodations for 42 people. As a sleeper, there will be berths for 32, with double lower berths on each side of the aisle, and upper

Crew will consist of a captain, a first officer and a flight engineer, plus a steward and a stewardess. A K.

AIRLINE TO HELP THE PRIVATE FLIER

T is frequently claimed that the airline operators are inimical to the private flier, and have been responsible for the legislation which limits use of the airways by the private operator But surely there must be some way of preventing hindrance to scheduled operation by irregular private operation, and in general the transport ople are most friendly to the stinerants. United Air Lines announces that the company will help the private owner in many ways; by furnishing weather information at all its stations; by providing hangar space at a number of airports, by selling gasoline and oil wherever such service is helpful; by providing mechanic service wherever such service is helpful and permissible. Nothing could be more indicative of friendly co-operation -- A. K.

WHY ALLOYS ARE NOT PERFECT

IT is accepted, at least theoretically, that all atoms in a metal would line up in perfectly ordered arrays like millions of dice which had been carefully stacked on top of one another, provided the metal could be frozen at absolute zero—459.72 degrees

below zero. Fahrenhelt—the point at which all gases would solidify and all molecular motion would cease. But there just isn't amy place on earth as cold as that. Consequently, whenever two or more kinds of atoms are mixed, they arrange themselves in a more or less disordered fashion, berealt is an aggregation of jumbled groups of crystals, analogous to millions of dice dumped helter-akeler m a box.

FREEZE METAL PARTS FOR EXPANSION FITS

B' utilizing the extremely low temperatures available with a mixture of Solox and dry-ice, a new method for cold-shrinking metal parts for "expension fits" elimnates both the expensive equipment and adverse chemical effects associated with previous brine techniques.

Dry-ice is solid carbon dioxide at a temperature of -109 degrees, Fabrenheit, which, in subliming, absorbs approximately 247 B.T.U. per pound Solox is a proprietary alcohol-type solvent and is favored for this application not only because it remains liquid at the low temperatures but also because of its non-corrove properties.

A mature of dry-see and Solox will produce a temperature of -97 degrees, Fahrenhett, which is considered suitable for shrinking internal parts larger than 9 or 10 inches in diameter. The part to be shrunk as immersed in the Solox, and pueces of dryne are added to keep the maxture "boilings" (gwing off carbon dioxide) until the part (gwing off carbon dioxide) until the part (gwing off carbon dioxide) until the part unum shrunkare. Solorat News.

'GIRO DELIVERS MAIL ON ROOF

IT is 25 minutes truck running time from the Camden Ariport, New Jersey, to the Philadelphia Post Office at 30th and Market Streets. A Kellett KD-113 Autogine makes the trip by air in five or ax minutes and shuttles back and forth from the Airport to the roof of the Post Office five times duly, carrying a full load of mail each time. Eastern Art Lunes, which contracted for this

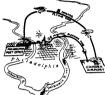

Taking off from a post office roof

One of our photographs above John Miller, veteran 'giro pilot, and nov a captain in the service of Eastern Air, taking off the roof after arm of less than 150 feet. The service has proved a complete success, and other cities such as Chicago, Mintual Case, Alfanta, St. Louis, Derroll, and Los Angeles are studying the problems and are exching to establish similar autogrom mil ferries. Certainly its application in such work is a "remarkable tribute to the utility work is a "remarkable tribute to the utility

AIRCRAFT AS AN

INVESTMENT

RAWSON LLOYD, of Aeronautical Se curity Research Corporation, writing in "Flying Facts," gives ten reasons for buying aircraft stocks Larger air forces are being organized in all countries; unfilled orders amount to \$250,000,000; huge aircraft orders of \$175,000,000 are to be placed by the Army and Navy during the year; Great Britain and France want to buy another \$100,000,000 worth of our air. craft; more efficient production has in-creased profit margins 37 percent; contractors on Navy orders are now allowed 12 percent profit instead of 10 percent; passen-ger air traffic has risen 28 percent for first five months of this year; plant expansion has been conservative; labor is not yet unionized; stocks are selling on a low pricetimes-earnings ratio. Even though these views come from the supposedly dangerous neighborhood of Wall Street, they must be regarded as reasonable.- A. K.

SEAPLANES CAN USE LAND AIRPORTS

AT least it would appear that seaplanes A can alight on land, from the exploits of Al Bennett at a commercial airplane demonstration given by the Avisiton Country Clab of Michaville, Long Island. Mr. Bennett used a standard Fiper Cab powered with a Listope motor and fitted with Country Cabo of Michael Country of the Avising motor and fitted with a Carlo was the fitting of a steel strip art" was in the fitting of a steel strip

screwed on the outside of the float keels. Yet Captain Bennett was able to land on the field, taxi, and take-off, without any aign of damage or even wear. Apparently seaplane floats have sufficient resiliency in themselves to take up the shock of landing.—A. K.

SENSITIVE

A CURRENT-detecting device so sensitive that it will measure the electricity carried by one electron traveling down a wire every five minutes, was recently described by Dr. J. S. Allen, of the University of Minnesota. The best previous device measures 20 electrons per second.

DROWNING TAKES

ITS SHARE

A PPROXIMATELY 7500 persons drowned in 1938, and almost exactly 50 percent of them did it during just three months: June, July, and August.

So says the National Safety Council in its 1939 statistical yearbook, Accident Facts. About 5000 of the total occurred while the

victims were swimming.

Two of every five drowning victims (both male and female) were under 20 years of

But listen to this, men. Five of every six drowning victims were men and boys.

ALUMINUM LUCGACE

CTYLED for the skyways and as trim and modern as the transcontinents sittliners themselves are aluminum alloy traveling bags, a part of the newest lungage line of the Metals Division of Erle P. Halliburton, Inc. Strong aluminum alloys which have been so thoroughly service tested and satisfactory in arginan construction, provide a logical material for these light, strong traveling bags and satisfaces.

Carefully designed in every detail, the stamped shells are heat-treated to provide strength, and finished in the patented natural Alumilitie finish to promote an attractive and durable surface. The interior of the women's cases is done in rich silk, with handy, removable dress hangers, rubber-ined commetic and bottle pockets, and a zipper-closung jewerly pocket. All models of the

Moisture-proof, light-weight luggage

Halliburton cases are equipped with rubber seal gaskets to protect the contents from monsture and dust. They have been subjected to submersion and artificial dust storm tests without the slightest damage to their contents. Because they are sealed artight against changes in atmosphere pressure when closed, high altitudes will not "pop" the stoppers in containers of lequids carried in them.

RESIN CEMENT AND HEATLESS CASTING

PLASTIC

TWO interesting and important reams which have been named Outck-set No. 1 and No. 2 have been announced by The Marblette Corporation Quick-set resins are liquid phenol-formaldelyde condensation products which are caused to harden without heat and pressure by the addition of an accelerating agent.

Outck-Set ream No. 1, when used as an

Quick-Set resus No. 1, when used as an adhesive, forms an insoluble, infinishle, transparent joint of iremendous strength. It is used for joining Lucite, Plexiglass, Marblette, wood, leather, casein and cellulose plastics, Formica, pressure molded plastics, and other materials.

Other uses include wood lamination and

impregnation, varnish, paper and cloth lamination.

As the hardening of this cement is strictly chemical reaction, air-drying is not neces-

ony me arenate corporation. Out of its element, yet this semplane landed and took off from the ground

sary for this material will set in the absence

Ouick-Set resin No. 2, obtainable in black and ivory, is used for producing castings in rubber (latex), lead, and glass molds. After casting, this resin will harden in 24 to 48 hours without the aid of heat

COLOR DETERMINER

AN apparatus which assures absolutely correct determination of colors at any Ta correct determination of colors at any time of day, irrespective of the surround-ing sources of light, has been constructed by Dr. Tryggve Johansson, of Upsala Uni-versity, in Sweden.

The machine, which is somewhat larger than an ordinary typewriter, produces an unvarying "mid-day light," by which is unvarying "mid-day light," by which is meant a light corresponding to that obtaining around noon on an overcast day This result is arrived at by using electric lamps equipped with special filters, by means of which a correct composition of light is achieved. The color tester also ex cludes all outer light sources, so that no sort of disturbing light is admitted. The samples to be compared—for example, a couple of pieces of cloth—are illuminated at an angle of 45 degrees from two opposite directions, and the observer is forced by the construction of the apparatus to study the samples at right angles Through this arrangement, no luster or shadow effects appear on the objects, which is often the e if these are lighted from one side only -Holger Lundbergh.

SHAKES HANDS WITH SHADOW

THE newest addition to the General Electric "House of Magic" at the New York World's Fair enables W A. Gluesing, director of the show, to say goodbye to his shadow, walk off the stage, and actually leave it behind And the audience seems to get the biggest surprise when he sits down in front of a curtain, gets up while his shadow remains sitting, and then shakes hands with his own shadow

The screen on which the shadow is cast 18 made of a phosphorescent material. The screen stores up the light which it receives from a powerful spotlight and continues to glow after the light has been turned off.

And so, when Mr. Gluesing stands or sits in front of the screen, all of it is "charged" with light except the part obscured by his shadow. He turns off the house lights, walks away, and all of the screen glows except the part which received no light because of his shadow.

Given a strong enough light, the screen will continue to glow for as long as 10

. . With his own shadow

minutes. The shadow can be wiped out and brought back again by turning on and off the red light of neon lamps. This is off the red light of neon lamps. This is because the red light does not "charge" the screen and the phosphorescent light given off by the screen cannot be seen in the intense red light of the neon lamps

MOTORING EYE HEALTH FOR 1940

ADVANCE information that health is being given important consideration in the design of 1940 model automobiles, along with mechanical perfection, comfort and safety was given recently at a meeting ponsored by Fisher Body division of Gen eral Motors Corporation at the Libber Owens-Ford plants in Toledo Those at tending the meeting learned that better visibility through laminated safety plate glass is to be stressed by several manufac turers as a factor for eye health and reduction of nervous fatigue

Dr. A. H. Ryan, Chicago research serentist, demonstrated how polished plate glass transmits true images, whereas objects seen through sheet glass sometimes appear distorted.

"The distortion of images seen through sheet glass in a moving automobile is a major cause of eye-strain and consequent

nervous fatigue," Dr. Ryan said. "In tests we have found that three hours of driving surrounded by sheet glass causes a 62 percent greater loss in visual efficiency than looking through polished plate glass. We also have found that people blink oftener when looking through sheet glass and that they can read faster through plate

"These findings indicate that plate glass and the clear view it allows provide greater safety on the highway, which will be recognized as an important factor when it is remembered that approximately 25 percent of all accidents result from faulty vision."

Dr Ryan described automobile driving a healthful exercise for the eyes, "provided

it is done under proper conditions. "Driving gives the eyes an opportunity for long-range gazing-a desirable change from the constant close work of office and factory But the eyes should be allowed to see the world as it really is, not as a caricature." Dr Ryan declared

WONDER DRUG

THE new chemical remedies of the Prontosil-sulfanilamide-sulfapyridine group are now being used to treat no less than 33 common disease conditions. They seem valueless, however, in the treat-ment of influenza and colds.

COFFEE PLASTIC

NEW plastic, developed by the H. S Polin Laboratory of Research in Physics, is unique, particularly from the standpoint of use in South America, in that it is made wholly from the green coffee bean and requires no additional raw materials. Coffee-plastic manufacture will be a highly self-contained industry, because the coffee provides its own chemical plasticizers and catalysts, and its own filler material Its by-products, furthermore, are sufficiently valuable in themselves to defray much of the cost of production.

The new coffee plastic can be produced in a thermo-setting or a thermo-plastic form. It can be produced in green, red, mahogany, brown, yellow, and ebony black merely by the chemical development of its own color-ing materials, in which the green coffee bean is unusually rich. (One of its by-

Distortion, caused by looking through safety sheet glass (left), and the clear view through safety plate glass

product fields will be that of vegetable can be made in varying degrees of hardness and resiliency according to the use for which it is intended. It can be molded, drilled, machined, sawed, and polished, and it can be produced with a wear-resistance superior to wood, cork, or rubber, and comparable with the best grade of linoleum. The thermosetting material can be produced with a compressive resistance of 8000 to 12,000 pounds per square inch, has good dielectric strength at low electrical frequencies, very slight water-absorption, and good resistance to weak acids, fruit juices, alkalis, oils, ketones, and other chemicals, and complete flame-conductivity resistance. It is odorless and tasteless, and it can be molded at pressures from 2000 to 5000 pounds per square inch

An important by-product of coffee-plasue manufacture is coffee oil This oil is rich in chemicals, contains vitamin D, and is suitable for a cooling oil and as a mixing oil for paints. It contains fertilizer and abecterial-growth speroces, and can be used in insectioneds, medicines, soaps, and locate. Other by-products are an emulaifying agent and a chemical for forming column. Other by-products are an emulaifying a column contains and a chemical for forming column. Other by-products are an emulaifying a column column column. Other by-products are not contained for course of coffering focures, coffee is already well known.

Concerning the cost of manufacture, a

Concerning the cost of manufacture, a bag of coffee containing 132 pounds, which it would cost the government an appreciable amount to destroy, can produce 40 square feet of plastic ½-inch thick, and approximately 1.25 gallons of coffer oil. The manufacturing process involves no unfamiliar machinery or special handling.

RUBBER TIRE INDUSTRIAL CLUTCH

THE same engineering principle that today is preventing thousands of motor-cars from skidding on wet and slippery pavements has made possible a new type

of mechanical clutch that has great promise

of wide industrial application. When the multi-vaned tread of the General Dual-10 and Dual-8 motor-car tres was perfected, it was proved that, under braking pressure, the many narrow vanes or riks of rubber aquirmed into a serpentiae form and clump to the road surface with a degree of adhesion never before thought possible. Adhesion being the principal job of a clutch, no matter where it may be used, it-was only a step from the multi-wand tire to the Atface rubber

Steps in producing a plastic from coffee beans. Left to right. Coffee beans; ground coffee after oil extraction; the extraction product; the reacted coffee plastic compound; and pellets produced by molding the reacted compound

clutch, the multi-vaned surface of which clings to steel with twice the friction coefficient of asbestos or other conventional clutch lining.

The Artiles rubber clutch, which is shown in accompanying illustration, already has replaced multiple dask and other plate clutches in various installations, with complete success. It has the advantage over the conventional datche in being much lighter, as well, having only three or four parts, as well, having only three or four parts, as companed with 75 to 100 pieces in the convictional clutch. The Artifex clutch is self-adjunsing while other clutches are

Two distinct types of lining are used, on both the expanding and constricting types of Airflex clutches. When excessive

slippage is encountered and where loads are to be picked up gradually, the use of friction lining is recommended. When the plan rubber squeegee-tread is used, a reasonable amount of slippage can be to erated if the engagements are not too fre-

The clutches are given special treatment to prevent disintegration by oil fumes. A special rotary seal has been developed to deliver air to the clutch, either by entering the shaft at the end or by a straddle-type

PAINT REMOVER

E XPERIMENTATION with solvents amid combinations of chemicals to make a milder paint remover resulted in a recently announced product called Presto. The remover contains no alcohol or caustic so-

lutions but is a combination of seven chemicals and, it is claimed, requires only five or ten minutes to work. The manufacturer also states that Presto seldom requires a second application, will not harm bristles on brushes, raise the grain of wood, or burn the bulk.

Three grades are available; Grade A for fine finishes and delicate woods, AA for general use, and AAA for any finish on metals.

PROBOSCIS

LITTLE things do count—heavily at times. Consider, for example, the mosquito's stinger, or proboscis. That pleasant little thing weighs just 0,0000006 of an ounce.

SILVER STEEL

POSSIBILITY of a broad extension of the marine uses of 18-8 stainless steel alloys is suggested by a patent recently granted on protection of the steel against seawater corrosion by addition of minute amounts of silver to the alloys, reports The Industrial Bulletin of Arthur D. Little, Inc. The peculiar corrosive properties of seawater have in the past been a serious, unsolved problem for stainless steel. If a portion of a stainless steel plate is covered by, say a barnacle, the difference in oxygen concentration near the exposed and unexposed surfaces will set up an electrical potential favoring the formation of chlorides of the metals in the alloy. Since these chlorides are soluble, they wash away, leaving the surface exposed for further attack. Thus a sub-microscopic pit forms and, as it deepens, the difference in oxygen concentration between the pit and the body of the metal increases and accelerates the corrosion within the pit. Ultimately the interior is honeycombed with such pits. although the surface may appear entirely unmarred; and the steel becomes subject to sudden and complete failure, almost

without warning. A solution to this problem, recently worked out by Professor R. S. Williams and consistent in Milliams and the Massachusett Inatitute the Massachusett Inatitute as of Technology, is based on the machinities of Technology, is based on the machinities of silver chloride for machinities and the silver added to the alloy will reduce the corrosion rate more than 80 percent, since as a protective coating. Only in alloys of approximately 18-8 composition (18 percent chromium and 8 percent nickel) does the chromium and 8 percent nickel) does the small amount of alley appear to be addeduced to the process of the small amount of alley appear to be addeduced to the process of the small amount of alley appear to be addeduced to the process of the process o

quately dispersed, but these are the most popular of the stainless steels.

Many advantages other than corrosion resistance are claimed for the silver alloys. Probably most important, since stainless steel is now considered unsuitable for many uses requiring high heat conductivity, is the reported increase of 26 percent in therconductivity on adding only 0.14 percent silver. Other advantages include aprovement in the case of machining and ability to take a higher polish. A very uni-form, highly polished surface in itself inhibits corrosion, since it makes inception of electrolytic activity difficult.

MILEAGE

MORE than one third the distance around the earth at the equator—8870 miles-is the distance traveled annually by the average American passenger car

TORTURE MACHINE THROWS 2600-Pound Punches

SCIENCE recently added a new punishment rack to its torture chamber—a 600-pound agony maker aimed at survival of only the strongest steel blades for use in steam turbines.
Built in the Westinghouse Research Lab-

oratories at East Pittsburgh, the novel machine subjects test parts to a concentrated dose of the brutal pummelling which full-scale parts must withstand inside a turbine.

The weaklings, those parts that are faulty in design, literally fall to pieces, but the sturdy metal martyrs can "take" as many as 10,000,000 beatings, and that's enough to guarantee them life eternal, for all practical purposes, in the production of electric power. These 10,000,000 blows are delivered in approximately 277 hours at the rate of 600 a minute, according to T. F. Hengstenberg.

research engineer in the mechanics division. who designed the machine.

A motor-driven flywheel throws the punch es at the test piece with a force of 2600 pounds behind every blow. Every time the flywheel turns it pushes a heavy spring to snap a steel lever up against the six-inch metal sample.

These metallic blows, Mr. Hengstenberg explains, simulate the force of steam rushing against blades in a turbine with a pressure

against blades in a turbine with a pressure of about 800 pounds to the square inch. Simultaneously, the test piece is immersed in a steam bath inside an electric furnace at a constant temperature of 850 degrees, Fahrenheit, identical with the temperature

inside a steam turbine at which the steel parts glow a cherry red. To duplicate the centrifugal force of the turbine blades, which often travel around their shafts at speeds exceeding 789 miles an hour, the machine pulls the test piece upward with a force of 9000 pounds by means of levers and springs attached to dead weights.

COMMON RAW MATERIALS GIVE IMPORTANT CHEMICALS

THE world's most important industrial chemicals are made from a small group of mineral raw materials, although the production of a single chemical may require an amazingly large number of other chemi-

cals, processes, and raw materials

If the chemist were given three wishes, as in the fairy tale, he would pick these groups of raw materials: 1, coal, petroleum, and natural gas; 2, sulfur and sulfide ores; 3, salt, brines, and sea water. These, with limestone, air, and water are most frequently used in manufacturing our chemical

Drs. R. N Keller and T. T. Ourke at the University of Illinois have been looking into the source of 150 important industrial chemicals, ranging alphabetically from acetanilide to zinc sulfate. They can be traced back to only 34 raw materials.

Consider ammonia, for example. It and the materials used in its manufacture include ammonia liquors, nitrogen, hy-

Above: Adjusting the "punching power" of the machine that tortures teel blades for steam turbines until they fracture as shown at left

drogen, calcium cyanamide, catalysts ar catalyst supports, peat, bones, animal ref-use, sugar beets, and the like. Ammonia liquors come from coal gas which comes from coal. Nitrogen comes from the air, hydrogen from water. In fact, all the ammonia sources can thus be traced back to air, water, coal, and limestone.

This digging back into origins is not just an academic exercise. It may very well aid a producer or owner of some raw material to plan manufacturing and dis-tribution of a product. Since transportation of heavy raw materials is costly, intelligent knowledge of what is needed ultimately to produce a product may allow shifting of industrial plants to more advantágeous locations.

Water and air are the most frequently used ultimate geologic raw materials—used 99 and 96 times, in the case of the 150

chemicals. Next in order are coal, 91; sulfur. 88; mineral salt, 75; limestone, 63; sulfide ores, 32; brines, 24; petroleum, 23; natural gas, 16; saltpeter, 13; potassium minerals, 11; gypsum, 10. The other 21 raw materials are used less than 10 times each.-Science Service.

GLASS-SANDWICH BRICK

A NEW glass building block containing an interior acreen of glass fiber that sharply reduces the transmission of solar energy was announced recently by the Pittsburgh Plate Glass Company.

The new block, developed by engineers of the Pittsburgh Corning Corporation.

screen in this glass building block reduces transmitted heat

gives a soft, diffused light that reduces glare of the sun. The decreased solar heat transfer cuts down the cooling load in air-conditioned rooms. The characteristics of the new glass block adapt it particularly to large areas where softer natural daylight 18 desirable.

Both the new and the conventional blocks are made by fusing, at high temperatures. two pressed, square glass cups into an all-glass wolded unit. In the newer design a berglas sheet is sealed between the block halves, forming an integral part of the finshed unit in the center of the block. As in the older design, the high sealing temperature results in the formation of a par-tial vacuum in the block interior when it cools. This increases the insulating value of the unit.

Variations in the effects desired may be had by changing the thickness of the fiber glas sheet. A typical unit of the newer de sign transmits only 55 percent as much energy as the older block, but 75 percent as much light with a marked increase in light diffusion

METHYL BROWDE AS INSECT "EXTINGUISHER"

METHYL bromide, sometimes used as a fire extinguisher, is proving even more useful as an insect "extinguisher" or fumigant, as it will in many cases kill insect gant, as it will in many cases kill insects without injuring the plants upon which the insects are feeding.

Methyl bromide is used—in control of the Japanese beetle—in the fundgation of fruits

and vegetables from within quarantined areas. It also has been found particularly useful for treating potted plants and nursery stock which may be infested with the larvae of this insect. After treatment the plants can be shipped outside the quarantined area without danger of spreading the pest.

TANK TRUCK FOR LIOURD CO.

NEW model EFH Mack truck recently A placed in service by the Cardox Corporation, of Chicago, is an example of the facilities developed by this concern for transporting liquid carbon dioxide at controlled constant pressures and in bulk quan-

Since CO₂ liquid has a vapor pressure which is dependent upon the temperature of the liquid, the pressure increases as the temperature rises. Prior to this development, liquid CO, has always been handled in con tainers in which the temperature of the liquid would become the same as that of the surrounding atmosphere. Pressures as high as 1500 pounds to 2000 pounds could, therefore, result in the small individual shipping cylinders. Containers for high pressure are necessarily of heavy construction so that large capacity containers were impractical and uneconomical.

Cardox transport equipment, such as that mounted on this Mack truck, consists of pressure vessels with relatively low working pressures as, for example, 300 pounds per square inch. Corresponding temperature at 300 pounds pressure is approximately 0 de-grees, Fahrenheit. This container is well insulated so that heat loss will be low and pressure rise in the tank will be slow. The liquid CO₂ is placed in the tank at a pres-sure appreciably below the working pressure of the vessel, and a pressure relief valve is provided which will open at the normal working pressure of the tank. With the open-ing of this valve, CO₂ gas is bled off from the top of the tank causing evaporation of liquid within the tank, the evaporation process cooling the contents of the tank and thus lowering the pressure so that the control valve will again close.

This truck unit can maintain constant pressure of 300 pounds over an indefinite period of time by bleeding off approximately

bleeding valve. However, if the truck tank is filled at pressure of 250 pounds, it will require several days before sufficient heat penetrates the insulation to raise the pressure to 300 pounds. A normal haul is of less dura-tion than the time required for the pressure to reach the point where refrigeration by bleeding begins; hence, in actual practice, no loss of gas is experienced in transit. The unit is equipped with a compressor type of liquid pump which enables liquid CO₂ to be transferred in either direction between truck tank and storage tank and additionally makes it possible to fill high-pressure shipping cylinders and containers.

FLAME-DESCATING

THE operator in the accompanying illus-THE operator in the accompany in tration is flame-descaling an 18,000and steel casting for a hydraulic turbine. Flame-descaling is a relatively new process for removing the scale from blooms, billets, slabs, forgings, and steel castings by means of specially designed oxy-acetylene heating

Flame-descaling a casting with a special oxy-acetylene heating head

heads. The process is based on the principle that when high-temperature is quickly applied to the scale (or oxide skin) on a piece of cold metal, the scale expands and breaks away from the base metal because of differential expansion between the scale and

Insulated tank truck for transporting liquid CO, at constant pressure

as pickling, sandblasting, and chipping. The casting shown here, for example, was flame-descaled in one fifth the time formerly required for chinning

SELF-CONTAINED UNIT HEADLIGHT

NE of the most significant developments in automobile headlights has resulted from three years of co-operative research and testing by the entire automobile and headlighting industry in colleboration with public authorities. This is

Headlight lens, bulb, and reflector in one unit for most new cars

the new Sealed Beam headlighting system which has been generally adopted for most of the cars to be announced this fall. The new system promises a great increase in safety for night driving for two reasons: the traffic beam is practically without glare; and, second, the lamps are estimated to give virtually their original illumination throughout the life of the lamp

The new headlamp is unique in that the source of light, the reflector, the lens, and the gasket are all assembled in a single, securely sealed unit. In other words, the headlamp is a single light bulb steelf, the parabolic reflector surface of which is allvered on the inside and cannot therefore be affected by dust or moisture. Two types of scaled beam units are available—one entirely of hard glass and the other a composite unit consisting of a metal reflector and a glass lens. The two types will be interchangeable in the recesses provided for them in the newer cars.

These units are relatively more expensive than the present bulbs but, considering the light efficiency as the new lamp ages, the increased cost over ordinary small bulbs loses its significance. Other advantages are permanently focused for best results. a wider and stronger country beam is given, while the traffic beam is thrown more sharply to the right side of the road and gives better illumination even far to the right of the shoulder. When the filament finally burns out the whole unit is thrown away and a new one installed.

FOR FUTURE DA VINCIS

ALWAYS a challenge to designers, world fairs have resulted in the development of a number of new architectural forms, many of which have later become generally adopted. It is perhaps in the bold use of

WHERE SCIENCE ENDS HOSPITALITY BEGINS

The Waldorf, for example, is a magnificent scientific achievement, not only dependent on science when it was built, but continuously dependent on many sciences for the efficiency of its operation.

But every man of scientific turn of mind knows what we mean when we say that hospitality, in his own home no less than in the Waldorf, is something warm, living and human that survives scientific detachment.

And it is that ability to preserve the human touch, in spite of all our clockwork schedules and efficiency, that gives the Waldorf its unique reputation for mantaining close, cordial and communicable contacts with its patrons.

Besides, this year, when you come to New York, you'll get so much science at THE FAIR, that it'll be a genuine relief each day to return to the hospitality of The Waldorf-Astoria!

new materials for decorative and artistic effects that the New York World's Fair, however, makes its most striking contribution to the progress of art and design. In this sphere, the Fair has given an imputs to the technological developments of the last few years which may hasten by years their general adoption.

general acoption. See the decorative use of Outstanding to the prediction of the control of the prediction of the prediction of the control of transparent varieties now available Domenico Mortelluto, for example, has achieved in his mural in the lobby of the De Pont Building, a design remniscent of stanced glass but with a refreshing balance of colors and textures attained by use of the soft and plastic properties of these new materials. The nue-foot cast-phenolic statues in the Federal Building, designed by E. H. Burdeck, highted from whish, provide a considerable part of the illumination in the large hall in which they stant. Many toon strikingly accents different portions of the grounds are faced with blastic materials.

The use of stainless steed as a sculpture material has been notably advanced at the Fair, as Dr. Gerald Wendt, Director of its Department of Science and Education, has pointed out. Robert Foster, a pioneer in the use of the welded steel sheet, has two gasante figures in this medium. His Winged Morency," floating in brilliant Winged Morency, floating in brilliant Ford Building, brings out to full advantage the lift, the apparent floating lightness of the speedy messenger of the gods, liss herois figure of a woman is notable for the long fold of cloth draped over her extended arms. The large mural in the French Psyllion

by Jacques Durand is done on wood, with synthetic lacquers containing colloidal gold In the focal exhibit in science, Allen Saal burg has used a new technique, painting large transparent murals on glass, using alcohol-soluble dyes applied by the air brush. Witold Gordon's mural, "Food," is done in rubber-base paint.

months are understanded by the fluorescent materials, have entirihed the color of the Fair and are largely responsible for its moturnal heavily. Especially striking is the device which sends a vertical beam of light from mercury lamps, set in the sod, upward into the trees. Each quivering leaf gloss with a soft green light resulting from the fluorescence of its chlorophyli. To many, standing new art form and most memorable feature.—The Industrial Bulletin of Arthur D. Luttle, Inc.

DETERMINATION OF COBALT IN STEELS

In the standard method of analysis of steels and alloys, sux to eight hours are required by an experienced chemist for a determination of cobalt. By further developments of an electrochemical ultration method, chemists of the General Electric Company have made possible accurate determinations of cobalt in alloy heast white there are being held at pouring temperature by the smelter. Thus a discrepancy in cobalt content of an alloy and be discovered before

Expensive castings are poured.

In the new method, a sample is dissolved in acid, the cobait oxidized with a definite excess quantity of standard potassium fer-

ricyanide, and the excess determined by titration with standard cobaltous nitrate solution. The amount of cobalt in the sample is calculated from the amount of ferricyanide need for its oxidation.

CAMERA BECOMES A

IMPROVED SURGICAL SUTURES MADE OF NYLON

N YLON mono-flament is now bong used to make suggest auture. Nylon, the same Du Post material that will enter into fine hoisery, it as man-made, protein-like substance derived hasically from coal sit, and water, characterized by extreme toughness and strength, and possessing the peacutar ability to be formed into fibers and nito various shapes such as bristles and theses.

The new autures have been tested by more than twenty important hospitals and medical centers throughout the country, and declared a marked improvement for dermal sutures. It is said that they are practically non-irritating to the tissues, do not deteriorate in the presence of infection, and

How Mickey Mouse joined our family

by Westinghouse

- "Plastic dishes with pictures of Mickey Mouse—how in the world did Westinghouse get into that line?" asked a buyer. Well, it's an odd story, showing how the logic of production sometimes leads to surprising answers.
- Among the many electrical products that we make are the outlets, switches, plugs, fuses and other little connections needed in a wiring system. They are known as Bryant and Hemco wiring devices, and are made in our factory in Bridgeport. In 1928, when the mazing possibilities of plastics were startling industry, we took over a nearby plastics plant to mould these various devices.
- The capacity of this plant was greater than our needs, so we either had to cut it down or find new uses for plastics. About that time, scientists created new plastics in vivid, rainbow colors—marvel-outly suited to tableware, toys, smokers' fittings and hundreds of such things. It seemed a long jump from dynamos and motors, but we had the plant and the plastics, so we plunged into the new field.
- Famous designers went to work — skilled tool makers made

hundreds of new dies — we hired salesmen who knew dishes and tumblers rather than switches and plugs —and almost before we knew it, had an important new business on our hands.

- · Our first big hit was with children. They were delighted with fascinating dishes decorated with pictures of Mickey Mouse, Snow White, and other lovable people who live in story books. We have sold millions of dishes glorifying Mickey and his gang! And millions of gaily colored spoons, plates, tumblers and kitchenware, all identified by the well known names they bear -Hemcoware or Safetyware. That ashtray on your desk, the plastic housing of your new electric razor or the beautiful plastic cabinet of your bedside radio-they probably are all of our make.
- Today, this plastics plant is busy with orders from chain and department stores from all over the country...from sales organizations who use these products for premiums and novelites...and from manufacturers who are using plastic parts in their products.
- To us Westinghouse people, trained as we are to do years of research before launching a new electrical product, this overnight success that seems almost to have come out of the air, is startling and refreshing. Actually, of course, it did take a lot of planning and good team work—but still, it's fun to look back and see how Mickey Mouse came to join the Westinghouse family.

her tread at places is more than three inches thick. They comprise the tire equipment of large LaTourneau Tournapull earth-mowing machines used by the Guy F. Atkinson Company, of Los Angelea, in building the Hansen Dam near San Fernando, California. These machines are capable of carrying 30 cubic yards of earth at a speed of 17 miles per hour.

Each tire, when inflated—the tube itself weighs 100 pounds—has a load capacity of about 12½ tons. Three men, using a specially designed derrick, require five hours to

change one of these tires.

Shipping of the tires necessitated the use of open-end railroad cars, as the doors on the ordinary freight and express cars were not large enough to get the tires through.

LUNG COLLAPSE TO

CONTROL TUBERCULOSIS

COLLAPSE of the lung for persons suffering from theoreulosis has been found by the Chicago Municipal Tuberculosis Sanlarium to be twice as effective a treatment as other measures directed against the control of the disease. A critical study of 7341 cases is reported by Drs. Frederick Tice and Allen J. Hruby of the Chicago institution in the Journal of the American Medical Association.

Of the 7341 patients observed, over a

6 1/2-year period, 3090 were subjected to lung collapse for more than three months, 337 for less than three months, and 330 had pneumothorax attempted. The other 3584 patients were controls.

Broadly, the results were twice as good with the treated patients as with the controls and were better still in comparison with the life expectancy of patients with open tuberculous as revealed in the medical literature—Science Service.

SIGHT AND SOUND TORQUE INDICATING WHENCH

A NEW type of torque measuring wrench which can be applied to any detachable socket having a ½-inch square drive opening, is now on the market. This wrench is of the reversible ratchet type and is designed to indicate right-hand torque.

With a wrench of this type, it is possible for the operator to tighten nuts or bolts even-

Uniform tension on series of bolts is possible with this new wrench

ly and to any desired tension or torque load. Closely limited torque application is now considered essential in many types of automotive, aviation, Diesel-engine and industrial work.

In application, the wrench may be used by utilizing either the calibrated scale which, by sight-reading, shows applied pressures of 20 to 200 foot-pounds, or by a sharp soundsignal which is given for any desired torque from 35 to 200 foot-pounds. The calibrated scale is read at a point where the index shoulder crosses the scale and the sound signal can be set by a simple device.

Accuracy of the wrench does not depend on gara, levers or dails. Although right-hand torque only is measured, the wranch action reverses for left-hand turning. The 36-tooth ratchet wheel, with twin double-tooth pawl of the reversible ratchet mechanism, makes possible the short operating swing of only 1%5 of a full turn. Wench action is instantive reversed by a flip of the shifter, located flush with the head.

HIGH EFFICIENCY RAILROAD BRAKE

A NEW type of railroad brake which will A bring high speed trains to a smooth, comfortable stop within 2500 to 3000 feet from 100 miles an hour—about half the distance now required—was announced recently by Edward G. Budd, president of Budd Wheel Company.

The brake diminates the century-old prin-

ciple of a metal "shoe" pressing against the rim or tread of the wheel. Instead, the engineers have patterned the new brake somewhat on those used in automobiles in

that a composition shoe is used. This shoe exerts pressure upon an air-cooled disk or drum, mounted on the axle inside the wheel to bring the train to a rapid, but smooth stop. Special control devices automatically prevent the wheels from sliding when the brakes are applied suddenly.

The new brake solves many of the problems of high speed train operation. The first is the effective control of a train traveling at high speed. "Flat wheels," bugaboo of railroad men, are climinated. Wheels and braking mechanism no longer will get

red hot on long grades.

The new brake was developed in the research laboratories of the Budd Wheel Company under the direction of C. L. Eksergian, chief engineer, who has devoted many years of research to the development of wheels and braking systems, in automo-

tive and other fields The first complete train equipped with the new brakes is the General Pershing Zephyr, of the Burlington Lines

PASSENGERS

N a year, the American railroads carry approximately 500 million assengers ... or equal to the combined population of North and South America, the United Kingdom, France, Italy, Poland, Spain, and Germany. More than a billion tons of freight are also handled each year by these carriers.

CIGARETTES ARE PIPE

FILTERS

THOSE people who started that the one-your-smoking cruze, and showed more than a million cigarette smokers how to do it by using two cigarettes at a time instead of one, are back at it again. This time it's a pipe!

They did the eigniette track with an aluminum holder in which you smoked one cigarette through another, the second ciga rette acting as a filter. Certified tests showed that this removed about 70 percent of nicotine, tars, and other undesirable ingre dients of cigarettes

Now they have succeeded in applying this principle to pipes. With the Zeus cigarette filter pipe you can smoke a "hodful" of

STEEL BENCH FOR PRECISION LATHES

NEW all-steel welded bench designed to provide a suitable support for preusion bench lathes, has been developed by the Engineering Department of South Bend Lathe Works. Extreme rigidity, the most essential feature for a bench of this type, has been secured by scientific bracing and generous proportions of all parts.

Smooth, flowing lines with rounded corners show a modernistic trend in shop

Rigidity and durability character-ize this new all-steel lathe bench

equipment that is not only pleasing to the eye, but highly practical. There are no sharp corners in which dirt or chips might collect, and no angular projections to form a hazard to the workman.

Around the top of the bench is a deep rolled rim which serves as a chip pan or oil pan. The sides and back of the bench are enclosed in smooth panels securely welded to the frame work. The front is open to permit the operator to take a comfortable working position either sitting or standing. The entire bench is finished in standard machine tool gray enamel.

The lathe motor drive equipment is lo-cated in the left side of the bench, while in the right side are three large drawers for storage of chucks, tools, and accessories. Each drawer has an individual tumbler lock combined with a latch and knob.

curiosity. Not even the inventor could foresee any practical implications to the achievement. He contented himself with writing a letter to the American Philosophical Society in Philadelphia about it.

Modifing backward it is different. This was probably the first time in history that propulson had been achieved and distance occured by means of an internal combustion engine, and the little best may have been the dim morning star of the motor age. The engine is described by Frank A. Taylor. Institution, In a described enaling of the mechanical collections of the U. S. National Museum.

Morey's model unfortunately is no longer in existence. The inventor did not wen try to get an American patent on it. All that or to get an American patent on it. All that with the property of the device, and the device of the device, we will be a summarized by Mr. Taylor as a vapor engine in which "a vecum was produced in the cylinder by firing an explosive mixture of air and vapor from common prod-spirits mixed with a small portion of spirits of turnion of the product of the produ

SUNLIGHT AND

AGRICULTURE

CCIENTISTS in the laboratories of the Jawains Sugar Planter's Association in Honolulu are now working on a project which promises to bring the sunlight factor within the realim of predictability for farming. Their experiments indicate that sunlight and its effects upon agriculture can be measured with a faur degree of accuracy. The implications of such a discovery for agriculture are fact-eachings.

The inquiry grew out of experiments which the Experiment Station has long been conducting in the water-absorption rate of growing cane. These experiments revealed that there is a direct and calculable relationship between the intensity of solar radiation and the "thirst" of the rane.

Indeed, so sensitive is the plant to the sun that a more who of cloud, passing in the sun that a more who of cloud, passing the sun that a more who of cloud, passing sun that a more who was a constant of the sun that a s

Under the direction of Dr. Harold L. Lyon, head of the Hawaiian Sugar Planters' Association Experiment Station, physicist Hugh W. Brodie has been working on this problem since 1930.

An outgrowth of these experiments has been a parallel study of the possibilities of a large-scale control of trigation based on sunlight data. This work is now in progress at the Hawaiian Sugar Planters' Association Experiment Station.

The value of such an inquiry may be realized from the fact that, for every pound of sugar produced in Hawaii, a ton of water must be used. Several of Hawaii's larger

AUTHENTIC REPRO-DUCTION OF PREMIS-TORIC AND MODERN ANIMALS in Royal Bronza Finisi 24 subjects, 35c each, OF GEFTWARES CORP. sugar plantations are operable only by irrigation—some plantations using as much as from 50 to 150 million gallons of water

With such a large consumption of water it is clear that considerable attention may be paid to conservation—and profitably, when the expense of pumping and ditching is taken into account. A natural control of sugar cane irrigation through the employment of solar radiation may have broad and far-reaching effects, in savings as well as in increased yields.

NITROGEN

THE nitrogen-fixation process, which recovers that gas from the air for use in our chemical industry and in fertilizers, produces about 4,000,000 tons of fixed nitrogen per year. This amount, however, represents only the quantity of nitrogen over one-fifth of a square mile of the earth's surface.

BETTER MAGNET WIRE

E LIMINATING the need for space-con-suming protective coatings in many instances, Formex wire, a new and superior magnet wire, announced recently by General Electric, is insulated with a synthetic resin which is tougher and more flexible than the conventional enamel coatings

Since Formex wire requires less space for insulation and protection, it gives the designer new opportunities to reduce the size of many products. Further, electrical properties are as good as those of ordinary enameled wires, and tests show that Former wire is considerably higher in resistance to abrasion and to the common treating solvents. When severely twisted and then subjected to a temperature of 125 degrees, Centigrade, for one hour, ordinary enameled wire cracks but Formex wire is not affected.

It withstands the operations of winding, assembly, and varnish impregnation much

ANOTHER

MATHEMATICAL

PROBLEM

BECAUSE of the interest shown in previous problems, we offer another by Lieutenant-Commander Kaplan. Any correspondence relative to this new brain-teaser should be addressed to him in care of Scientific American, 24 West 40th St., New York, N. Y.

The problem: A hole 2 inches in diameter is drilled through a solid cylinder also 2

inches in diameter, in such a way that the axis of the drill is perpendicular to, and intersects, the axis of the cylinder. What is the volume of material removed?

The solution will be given in these columns next month. Meanwhile, can you obtain the same answer as the author? His value was 5½ cubic inches

better than commercially available enameled wire. It can be used to advantage in nearly all applications where enameled wire habeen used, and in addition it can be utilized in many applications to replace enamelcution, enamel-paper, or other fabric-covered wires where formerly a protective wrapping was necessary.

NEW CASTABLE

REFRACTORY

An a result of its recent development work on castable refractores, Johan-Manville announces a new light weight Fire-crete for making special refractory shapes, for replacing difficult brick construction for hung furnace doors, and for making small monolithic linings. The new product is suitable for working temperatures up to 2290 degrees, Fahrenheit.

Accepted Laboratory and service tests

Accepted housement service tests have shown that has least addition to this line of products, widely used by industry for many years, possesses an exceptionally low heat storage capacity. This is of special importance in intermittently operated furnaces, since appreciable quantities of heat are wasted in heating heavy fire brick and then allowing the furnace to cool. Light weight Firecrete has been shown to be weight Firecrete has been shown to be tarding heat, while having only half its weight. Also, its resistance to apalling is such that it will withstand direct exposure to fame temperatures.

Sixty-five pounds of the material are required per cubic foot of finished construction. It can be used to form any required refractory shape. This is accomplished within a short period of time simply by mixing light weight Firecrete with water and casting it into a form. Twenty-four hours later the shape is ready to be placed in

VERSATILE SURFACE FINISH

SAID to give a hard, flick-proof finish, with perfect adherence to most metals, a new urea formaldehyde finish, which is called Ultrakote Synthetic, has been an-nounced by C. W. Haynes Laboratories, Inc. The finish it produces has the appearance of porcelain and is much tougher. It will stand denting, bending, hammering, and general abuse.

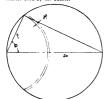

Ultrakote Synthetic can be used on any production metal, ranging from the manufacture of delicate jewelry to heavy machinery, including the following: metal kitchen cabinets, stoves, refrigerators, ironers, washing machines, clocks, office machines, and many other applications. It can be applied by spraying, dipping, or roller coating. It bakes to a tough, flexible finish at 150 degrees, Fahrenheit, in 30 minutes.

It can be furnished in either water-white clear or any other color, and the "clear is claimed to be non-yellowing.

SOLUTION OF LAST MONTH'S PROBLEM

AST month, in response to many requests, mathematically minded readers. Briefly, it was required to find the length of a rope with one end tied to a cow and the other to the edge of a circular pasture 200 feet in diameter. The rope allowed the cow to graze over half of the total area of the pasture.

The solution of this problem, as outlined below, requires the use of the calculus. Reference to the illustration will clarify the symbols used by the author.

The area encompassed by the radius arm o is given by the integral

This may be changed over into an expression involving only the one variable, 6, Since

$$\rho = 2a \cos \theta$$

and

 $d\rho = -2a \sin \theta \ d\theta$ We have, therefore, by making this sub-

$\int 2 (2\pi \cos \theta) \theta (-2a \sin \theta) d\theta =$	
-4a³∫0 sın 20 d0	
for simplification, we let	

If, for simp y = 20

dy = 2 d0and the expression for the area becomes

$$-a^3 \int y \sin y \, dy$$

Integrating between the limits $\theta = \frac{\pi}{2}$ and $\theta = \theta_1$,

which for y will be

$$y = \pi$$
 and $y = y_1$,
 $a^1 \left[y \cos y - \sin y \right]_{-1}^{y_1} =$

$$a^{*} \left[y_{1} \cos y_{1} - \sin y_{1} + \pi \right]$$

Since, by the condition of the problem, this area is to equal one half that of the circle

$$a^{1} \left[y_{1} \cos y_{1} - \sin y_{1} + \pi \right] = \frac{\pi a^{2}}{2}$$

$$\sin y_1 - y_1 \cos y_1 = \frac{\pi}{2}$$

The value of y, which satisfies this equation may be determined by constructing a table such as that shown below, and successively reducing the error of approximation to whatever degree desired.

From this table, it is evident that y₁ = 109°11'18".9 (very nearly)

$$\theta_1 = \frac{y_1}{2} = 54^{\circ} 35' 39''.5$$

and the corresponding value of ρ , using 200 feet in place of 2a, will be ρ₁ = 200 cos 54°35′39″.5 = 115 87 feet

yı (degrees) 110°	yı (radians) 1.91986	cos y ₁	y ₁ cos y ₁ .65663	sin y ₁ .93969	sin y ₁ y ₁ cos y ₁ 1.59632

You Can Influence Others With Your Thinking

TRY IT SOME TIME. Concentrate intently upon another person seated in a room with you, without his noticing it. room with you, without his noticing it. Observe him gradually become restless and finally turn and look in your direction. Simple—yet it is a positive demonstration which can be projected from your mind to the consciousness of another. Do you realize how much of your success and happiness in life depend upon your influencing others? Is it not important to you to have others underwand your point of view—to be remoterated your point of view—to be receptive to your proposals?

How many times have you wished there were some way you could impress another favorably—get across to him or her your ideas? That thoughts can be transmitted, received, and understood by others is now scientifically demonstrable.

KEYSTONE

THE KEYSTONE K8

is one of the smallest movie cameras in the world, being small enough to slip in the pocket of your coat.

It's accurate and economical and simple to load. There are no sprockets, loops or complications of any kind.

Can be used for color pictures as well as black and white. Takes either single or double width 8mm film

F3.5 lens interchangeable with fast or telephoto lenses-3 speeds, direct vision finder, built-in exposure chart and many other advantages.

Conducted by JACOB DESCHIN, A.R.P.S.

WHAT POSE?

ONE of the worst bugaboos the nonprofessional photographer has to encounter in his camera work is the selection of a pose suitable to the subject, and one that gets away from the usual thing. Gen-

erally speaking, the head may be posed in one of three principal positions with relation to the camera—full face, three quarter view, and profile. But such a rule is much too vague, almost too obvious, to be of real use when the purpose is to obtain a portrait that is alive with personality and not merely a likeness, or what is presumed to be a likeness. Moreover, a true likeness is not merely a physical resemblance, but a character im-

Posing may broadly be classified in two divisions—the formal and the informal. The formal pose is ordinarily associated with the studio or the carefully arranged set-up the studio of the carefully arranged services by artificial light at home. Figure 1 is an example of this type of portrature. It is the so-called "professional" portrat type, in which the subject is portrayed in conventional style. Both subject and photographer are conscious of engaging in a routine, a sober, methodical routine the end result of which is the familiar "studio portrait." Not that this type of portrait is a poor likeness or lacks character, but the personality is restrained; friends of the subject who see the picture do not quite recognize the person they know in life.

By contrast, examine Figure 2 and see the difference. This is the subject as we the difference. Into 18 the subject as we know her, smiling easily and gracefully; vibrant, sparkling, alive. Taken in the stu-dio, also, the method employed was radically

different from that used for Figure 1. The subject lighted a cigarette and was allowed to act naturally, to converse and generally to be "her self." When things looked ripe, the shutter was clicked and a precious moment was caught forever. Figure 2 is as much of a portrait as Figure 1, but which would you vote for if you had to make a choice between the two for a prominent

place on your bureau?

Figure 2 is an example of the modern treatment in portrasture, and so are the others reproduced here. Figure 3 is an outdoor shot in the informal manner. A miniature reflex camera was directed from overhead to record a characteristic pose and expression, entirely unrestrained and completely at ease. It is easier outdoors to make shots of the informal type with success, partly because of the diffuse and all-embracing nature of daylight, which permits exposures without having to be too much concerned with light arrangements. partly because subjects seem to be less camera-conscious outdoors. This is one reason why one frequently hears the comment that "the best picture ever taken of me was a snapshot at such-and-such a picnic" . . . or boat ride or hike.

Figure 4 is another indoor portrait by icial light. The subject, seated on a bench, leaned back, resting on her hands and turning her head toward the camera In the final printing it was found that the best result could be achieved by selecting the head alone and enlarging that to the full dimensions of the print, and Figure 5 shows how this was accomplished to the great enhancement of the result. Incide ally, many a portrait negative may be improved by the simple expedient of deleting the non-essentials and concentrating on the

Figure 3

face alone. The angle of the head adds considerably to an impression of liveliness, gayety, movement.

Rules, they say, are made to be broken hut here is one that you will do well to follow: never have the portrait subject facing the camera with both shoulders on a line with the lens. Have one shoulder nearer the camera than the other. When

Figure 4

the subject then turns her head toward the camera, the result will be much more agree able. Thus, Figures 1 and 4 were posed with one shoulder toward the camera, and Figure 2 with the shoulders at a slight

Figure 2 with the annuours at a magning angle.

The lighting arrangement for Figure 3 and 4 consisted of a main, diffused light, combined with a soft apollight; Figure 2, apollight and a soft main light from below, and Figure 3, daylight, with the sun formulabing both general soft illumination and a spollight effect.

But why is the subject always smiling, one singlet saik! The answer to that one in: the subject is more characteristically presented in this way. She is at her best

Figure 5

and most revealing when she smiles. Another subject might be untruthfully photographed while smiling, but whether the subject should smile or not is entirely an individual question. One cannot make generalizations; study the subject and record the most favorable and attractive pose and expression.

WHY A FILE?

YOU do not have to have a regular photographic filing device of any kind. You may store your negatives in ordinary envelopes and keep them in the bureau drawer, or in a cardboard box of some sort. drawer, or in a cardboard box of some sort.
This kind of makeshift arrangement may be good enough for your purposes. But for those industrious workers who accumulate large numbers of negatives, particularly iate large numbers of negatives, particu-larly three the negatives vary in size, a somewhat more elaborate system will be found not only convenient but essential. Especially will this be true for the man who intends now and then to dabble in journalistic photography where the shilly to find negatives quickly when needed is

COMBINES THE EASEL AND PAPER STORAGE CABINET IN ONE

Here's an enlarging easel combined with a paper storage box that reduces the movements involved in the en-larging routine to a minimum. The easel is actually the cover of the paper storage box and requires but the lifting of the cover to obtain a sheet of paper

Margins are easily and accurately controlled on this all-metal easel by simply pulling out a lever The white matter surface facilitates focusing matte surface facilitates focusing image arrangements Margins are automatically correct and even, with appropriate border. The PAPER (up to 14 x 17 inch size) is right in the storage cabinet which is the base of the easel—available at a second's notice by just lifting the cover.

HERE ARE A FEW OF ITS

- t. Locks in position the upper edge of the paper, before removing the hand when locating the paper on the ease! 2 Paper held securely at this stage by spring hinges.
- Control by single lever of both upper left corner paper stops, with provision for unequal margins of desired
- Unlimited widths of white borders from 3/16" to 134" indicated at a glance in scale.
- scate.
 5. Opening of frame (A) in advance of member (B) graduated by stop-acrew 6 Paper storage, light proof, drawer measuring 15 7 18 x 134
 7. Non-skid corrugated rubber on bottom. Beautiful finish

Fourth Annual SCIENTIFIC AMERICAN AMATEUR

PHOTOGRAPHY CONTEST

EVERYONE who owns a camera has Le chance of winning a valuable prize.

Make plans now to enter your prints in Make plans now to enter your prints in this contest. You may enter any or all of the three divisions, but not more than two prints may be entered by one con-testant in any one of the divisions.

Specific rules for this contest were pub-lished in our September number. Be sure to read them before you submit

In each division there will be prises of two Longines watches—"The World's Most Honored Watch"—and two Federal Enlargers, as well as five Honorable Mention Awards. This Contest Closes December 1, 1939, at Which Time All Entries Must be in the Hands of

Photograph Contest Editor, Scientific American

24 West 40th Street New York, New York of the utmost importance. The lack of a good system may frequently mean the dif-ference between a sale and a missed opportunity to cash in on one's hobby.

FLOWER CLOSE-UP

POR rendering details in flowers, the close-up supplementary lens is frequently employed to advantage. The picture of hollyhocks reproduced here, for example, was made with a miniature reflex equipped

"Hollybocks"

with a proxar supplementary lens which permitted an approach to the subject much closer than that possible with the unaided lens. Incidentally, the picture shows the flower in several stages of development, from the closed bud onward. In the present instance, some foreshortening may be seen in the near petals of the largest blossom, although it does not appear to be objectionable.

FIFTH ROCHESTER

INTERNATIONAL SALON

ENTRIES are now being invited for participation in the Fifth Rochester International Salon, to be held at the Rochester Memorial Art Gallery, Rochester, New York, from January 15 to Febru-ary 25, 1940. The closing date for the submission of entries is December 14. Entries are divided into commercial and pictorial groups. Fee is \$1 which includes the right to submit to the maximum of 6 colored lantern slides, 4 monotone prints, 4 color commercial prints, and 4 color pictorial prints.

VIEW CAMERAS

IN DEMAND

RECENTLY we have been noticing a considerable revival of interest among amateurs in the use of the view type camera-Particularly does this seem to be true of the 4 by 5-inch view, such as the Kerona and the newly introduced Crown. Secondhand view cameras of this type that appear in the stores do not seem to stay very long and one frequently hears favorable com-ments concerning the use of a type of cam-era that has usually been associated only with professional studio workers. While the

view camera, even the 4 by 5, is limited because it has to be used on a stand, many find it ideal for indoor portrature and other subjects; even landscapes. The 4 by 5 size, the "minature" of the 8 by 10 and 11 by 14, is easily carried in a small fiber case, to gether with the necessary film holders and so on.

PHOTOGRAPHING THE TOY POMERANIAN

A WALK in the park for the express purpose of making a photograph of Sandy offered an unforeseen problem. Sandy was obedient enough and would stay in one place for minutes at a time, but be seemed

to be fraghtened at the sight of the causer and would not behave normally Sometime-he cowered; at other times he was higher and nervous. One of the difficulties was getting his ears to stay up. This was finally accomplished, after many attempts, he someone standing just behind the photographer and, by one sign and another, convincing some standing just behind the photographer and, by one sign and another, convincing the state of t

THE CAMERA SISSY PHILOSOPHY

PERSONALLY, we like to buy a camera in a brand new condition, never handled before outside the photographic store. We like to have the feeling that any wear and tear accruing to a camera has some as a result of having been handled and used by as in the course of our picture-making activities. As time goes on and the camera we had used it frequently. The camera, by these services of the camera in the camera we had used it frequently. The camera, by these services of the camera and the pictures we made with it.

We admit that, like other camera users, we desire occasionally—and, when we can afford it, fulfill the desire—to trade in our earners for a new one, one equipped with the newer gadgets. They are hard to resist, these handsomely contrived, new camera models, not only because they are good to look at but the few gadgets are real improvements and signify advances in camera design. Nevertheless, no matter how

"SO YOU WANT TO TAKE BETTER PICTURES"

By A. P. PECK
Associate Editor, Scientific American

IS THE ONE BOOK

that shows you, simply and in understandable

language, how to take the best pictures under all conditions.

"Pictorial appeal and technical excellence" are yours for the choosing when you anap the shutter. You must first, however, be familiar with certain fundamental of composition and camera operation. These fundamental are difficult to dig out of the average book, but not when you have a copy of "So You Want to Take Better Pictures" at hand. You learn as you read, easily, pain-leasly, without having to wade through a mass of material that holds no immediate interest.

Written expressly for those millions of camera owners who have their developing and printing done at the photo shops, the lessons which it teaches are simple and straightforward, uncomplicated by formulas and directions meant only for the darkroom fan.

Profitable Photography with the

Miniature Camera

By Edwin C. Buxbaum, A.R.P.S.

BESIDES having a considerminiature camera, making trick "shots," art photographs, and the like, you can also use it for special paying work. This little paper-bound booklet of 72 pages tells not only how to make interesting photographs that are salable to news agencies or magazines but also gives many clues to the very large number of types of photographs that can be sold. For those who wish to mix profit with pleasure this booklet should prove most helpful.-\$1.10 postpaid.

For sale by

SCIENTIFIC AMERICAN 24 West 40th St., New York, N. Y. to be scratched or broken. You should be as careful of these as you are of the camera lens itself, for it must never be overlooked that the filter or supplementary lens is placed over the taking lens and that any damage suffered by these elements will have its effect on the negative.

WHAT'S NEW In Photographic Equipment

If you are interested in any of the items described below, and cannot find them in our advertising columns or at your photographic desire, we shall be glad to tell you where you can get them. Please accompany your request by a stamped entelogy.

Zeiss 6 by 6cm Ikoplex III (\$199): 21/4 by 21/4-inch twin-lens reflex camera equipped with Carl Zeiss Tessar //2.8, 8cm

(31/s inches) Spring pressure plate assures film placement in focal plane of lens. Tessar matched with 1/2.8 finder lens of same focal length, projecting image of subject on plano-convex focusing screen. Illumination uniform over entire

screen area. Four-times magnifier covers enscreen area, rour-times magniner covers en-tire focusing screen. Quarter-turn wheel focuses four feet to infinity. Scale on focusing wheel shows depth of field. Albada eye-level finder in which front element tilts forward and back as lens is racked out and in, correcting for parallax at all distances. Operating lever, with one smooth movement, simultaneously winds both film and shutter. Counter dial shows number of exposures made. Half-turn of lever advances film, spacing negatives evenly and winding shutter with one motion. Shutter is Compur-Rapid with speeds from 1 second to 1/400, bulb and self-timer. Signal shows whether shutter is discharged (black), wound (red), or set on self-timer (white). Shutter release adjacent to operating lever. Shutter speed and lens aperture settings controlled by levers on each ture settings controlled by levers on each side of shutter and visible in separate windows on top of camera. Double exposures and skipped frames eliminated by coupling of film-transport and shutter-winding mechanism. Tripod socket accepts standard American screw. Eyes for carrying strap. Standard 37mm slip-on filters and lens shade, as well as new Zeiss Ikon 35.5mm screw-in filters, fit lens. Film is loaded in usual way, then advanced until arrow (on paper leader of all film) lies between white dots on inside of camera. Hinged back is then closed and automatic counter mechanism goes into action.

BEE BEE ATLAS TRIPOD (\$7.50): For all types of cameras, including 5 by 7 view and cine cameras. Three sections, all chrome with satin finish. Has reversible chrome with satin finish. Has reversible feet, peg on one side and rubber tipped on other. Weight three pounds. When closed, legs 23 inches long; open, extend to 60 inches. Tripod guaranteed against mechanical imperfections. Packed in weather-profed tubular container which may be used as carrying case.

UNIVER MICHOGRAPHIC ENLARGER (\$27.50): Incorporates automatic film pressure re-lease, which permits sliding negatives with-

inches. Chromium plated. Head holds camera either horizontally or vertically, as desired. Complete with adjustable leather strap.

HURO DUTTICAL SIMP RULE (\$1.50) · Made of engraved tainless sete, 6. 1/2 inches long by I inch wide by I/8 of an inch thick, this rule gives photographers necessary information about lenses, focal lengths, magnifications, and measurements. For example, rule gives depth of field obtained when focal length of lens and sperture are known, assuring sharp enlargements of great djameter. Rule also constains, conversion tables—fahrenheit to centigrede, ounces to ce, mm to inches, garken to grans.

"Curves and Clouds," by Frank A. Richardson, with an Auto Rolleiflex . . . 1/100 second at F/8

Composition is Easy with a Rolleiflex

E VEN the beginner will find it easy to make sharp, well-composed pictures with a Rollel camera. Por composition, as well as facusing, is done on the ground glass screen. You see each picture as it is going to appear in the finished print. There's no parallax—no view finder—no range finder through which you have to squint. And the extra fast finder lens (on exclusive Rollei feature), renders a brilliant image even when the camera's lens is stopped 'way down to 11, 16 or 22.

Moreover, you get pictures of a practical size—twelve negatives 21/4" x 21/4" on a roll of standard, easily obtained 120 or B2 film. Makes beautiful Dufay-

color shots. Kadachrome cut film or 35 mm, rolls may be used with special adapter backs which are quickly attached.

There are now five different models from which to choose, priced as follows:

Rolleicord Ia, Zeiss Triotar f/45 lens in Compur shutter \$57.50

JACOB DESCHIN, conductor of our "Comera Anglea" department, suit answer in these columns questions of general interest to ameture photographers. If an enswer is desired by mail, enclose a stamped, addresseds to draw comparisons between manufactured products nor to advise on the purchase of quipment or materials.—The Edition

Q. I would like to get a picture of the moon, using a 3-inch refractor made by Bausch & Lomb prior to 1900. The objectiv is clear and I would use a 1-inch eyepiece. It is my understanding that iff should use a amera, it would be used simply as a film holder and the lens would be removed from the camera. I would like your advice as to the mechanical arrangement of the equipment; also as to the type of film to use.—J. C. C.

A. The procedure sometimes employed is to remove the eyepiece of your telescope and attach in its place the lightest ground-glass camera you can find. The camera lens is removed and focusing and exposure is done as normally. Very fast film, such as Super or Superpan Press is required and an exposure not exceeding one half second.

The correct focus must be found by trial and error because astronomical telescopes are corrected for the visual, not the chemical (photographic) rays. This experimentation is done as follows: Focus with the eyes as usual, getting the image as sharp as possible Now, moving 1/16 of an inch at a time, rack the film plane forward, making an exposure each time you have moved the film plane to a new position. Develop the negatives and study the resulting pictures, from which you can select the one that appears to have been focused the most sharply Mark the point of correct focus in some permanent way so that all you will have to do in future is to set the film plane at this point without further focusing. Incidentally, the negatives will provide a test of the required exposure. If the negatives are too dense, this will mean that a shorter exposure than one half second may be given.

may be given.

Another method, using a reflecting telescope, is described by Harold A. Lower in his article on "Celestial Photography" in "Amateur Telescope Making." The image of the moon at the focus of a six-inch mirror," writes Mr. Lower, "will be about half it may be magnised by an eyeplece to about an inch, and still be bright enough to photograph with an exposure of less than a second. Use an eyepiece of about one-inch focus, and project the image of the moon on a sheet of ground glass. Determine the distance from the cyspice which is

required to produce an image one inch in diameter. Then make a box to mount over the eyepiece, which will hold a plate-holder or ground glass focusing screen at the proper distance. There should be a door in the side of the box, so that one can adjust the eyepiece until the image of the moon is sharply focused. A small reading glass is quite a help in determining when the image is the sharpest. When the focus is the best obtainable, replace the ground glass with a plate-holder. Have an assistant hold a sheet of black cardboard in front of. but not touching, the telescope. Then remove the slide of the plate-holder, look through the finder and make sure that the telescope is centered on the moon. exposure is made by moving the cardboard edgewise from in front of the telescope, and replacing it as quickly as possible. Be care-ful not to jar the telescope. If the exposure is short enough, the motion of the moon will not be rapid enough to cause a blur, even if the telescope is not equipped with a clock drive." For further details we suggest you consult the article, which appears on page 254 of the 4th edition of "Amateur Telescope Making.

Q. I have samers with f/s.1 lear. Unfortunately, there is a nick on the branches of the German manufacturer are in New York, I am unable to have the lean spolladed. Do you know of an optical concern which will pollade have the lean store comes to work, under what conditions would the nick be the least discountible on the negative? The least discountible on the negative? Canada Balsam, or blacken it to a reid reflection?—I reflection?—I reflection?—I would be negative?

A. Although there is no manufacturer's "branch" in this country, the importer of your camera can undoubtedly help you.

your clamera can undoubtedly heap you. Concerning your last question, Arthur Lockett, author of "Camera Lenses," "A "cracked glass may not input; the performance of the less unless the outlies of the crack is, so to peak, markedly prismatic or irideacent in effect." Even then, he suggests that the lens may be made to work satisfactorily by paliting a narrow line of opene black twarish around the crack is of opene object warnish around the crack or

- nick. "This most probably will not above at all on the scene," he adds, "and will only subtrast is indicationally from the amount of light Similarly, a broken lene nawy be found to be about the bland of the control but if this is difficult, the "Diamond coment used for mending china, etc., will answer, or even a strong, hot pelatine solution." We would suggest you make several exposures with your lens as it stands and carefully examine the resulting negatives; if you can detect no real fault continue to use the lens as it is. Otherwise, ask the camere importer to percommend a good lens repair firm.
- Q. Occasionally I have to turn out a large number of prints and prefer to keep them all in the wash water until I get through with the entire batch. This may take several hours and the first prints will therefore have to stay in the water all that time. Will excessive washing hurt the prints?—L. K. M.
- A. Excessive washing sometimes causes frilling. An effective preventive that has been used with large prints, such as photomurals, that have had to be left in wash water overnight, is to add to the wash water about 5 percent of sodium bisulfits.
- Q. Please advise what model or number motion picture camera made by Eastman would be most suitable for a beginner—also projecting equipment.—T. S. C.
- A Queries concerning the equipment of a particular firm should be addressed directly to that firm as they are in the best position to give advice concerning cameras and equipment of their own manufacture. Accordingly, we have forwarded your inquiry to the Service Department of the Eastman Kodak Company.
- Q. I have heard it said that when photographing at high altitudes, it is necessary, because of the increased brightness of the light, to decrease the entire of the light, to decrease the should the exposures be?—S. E. L.
- A. That depends on the altitude. For a general example, at 2500 feet, give three quarters the normal exposure; at 5000 feet, two thirds; at 10,000 feet, one half, and at 15,000 feet, one third.
- Q. In developing roll film in a tray by the see-saw method, I frequently have trouble in getting the film into the solution evenly. Can you suggest a remedy!—W. B.
- A. Simply immerse the film in water before starting development. This will have no effect on the latent image but will make the film limp. Developing will then be even and you will avoid the possible danger of having air bubbles form on the film.
- Q. I would like to study photography, especially motion picture work. Will you please suggest some schools? I would also like to knew what company sells motion-picture equipment.—S. C.
- -S. C.
 A. Two schools which have special departments for the study of motion picture photography are the New York Institute of Photography, 10 West 33rd Street, New York, New York, and the American School of Photography, "8501 Michigan Avenue, Citicago, Illineis, Both schools offer resident and correspondence courses. A card

addressed to the schools will bring literature and complete information.

Motion-picture equipment may be purchased in practically any photographic supply house. Some of these companies are listed in our advertising columns. They will be glad to send catologues and prices if you will serte them.

- Q. Do you know where I might find a table showing emulsion speeds of various films recorded in both Din and Weston, or a table to convert Din readings?—W. W. M.
- A. In the United States, film emulsion speeds are rated either in Scheuner or Weston. Din ratings are used in Europe. A conversion table that includes American Scheuner (as distinguished from European Scheuner (as distinguished from European Scheuner (as distinguished from European than the American), Weston, Din, and H.B.D. speeds, in included in "Practical Speeds of Jilms and Plates," a list of film speeds rated in American Scheuner degrees. Meter Manuel, by Joseph M. Bing, F.R.P.S. published by Photo Utilities, Br.P.S.
- Q. I have an old 9 by 12cm Bakelite film-pack adapter in which the grooving has broken off, causing light leakage. I understand that it cannot be repaired. What would you advise?— A. H. W.
- A. Since the adapter was molded in one piece, special grooving machinery would be needed to put it in working order again and this is obviously out of the question because of the cost involved. The only remedy is to have a repair man fit a 3½ by 4½ kit into the broken adapter. While the size of the negative is thus reduced, the difference is rather alight.
- Q. Can you supply a formula for making a gum similar to that used on postage stamps which I can apply to the backs of small prints and which will need simply to be moistened before use?—H. C. M.
 - A. In five ounces of heated water, stir: 10 ounces of fish glue or liquid glue 5 ounces of liquid glucose

5 ounces of liquid glucose 5 ounces of denstured alcohol Few drops of carbolic acid

Thin the resulting solution with water to the desired consistency and brush the backs of the prints. If the prints are to be trimmed, apply the gum before trimming and trim after the gum has dried.

- Q. I am undecided whether to purchase a camera taking only roll film or one equipped only for filmpack and cut film holders. Can you give pros and cons as to which is more advantageous, roll film or filmpack?—R. S.
- R. S.

 A. Filmpacks are relatively easier to load
 than roll film, although with practice the
 latter may be loaded almost as quickly;
 furthermore, the roll-film type of camera
 requires opening the camera to loade. Roll
 film is easier to develop because an entire.
 In the case of filmpacks the films have to
 hendled individually, although such as are
 the compact of the compact of the compact of the
 roll may be developed at the same time.
 In the case of filmpacks the films have to
 hendled individually, although such as are
 compact of the compact of the compact of the
 compact will also take cut film which is
 usually cheaper than filmpack and affords
 a creater water of emulaious than roll film.

THE GLASS GIANT OF PALOMAR

By David O. Woodbury

MAINLY this most readable book con cerns the human side of the 200-inch telescope, what went on behind the scenes within the broad circle of scientists and engineers who conceived it, planned it, gradually evolved its details and then built it The swiftly moving narrative begins with Hale, the prime mover, and proceeds steadily down through to the present year (completion of dome and of mounting, grinding and polishing of mirror up to final parabolizing). For two special reasons it is authentic: first. the author, an outstanding contributor to first-rank magazines, is a telescope maker, hence closely comprehends his subject; second, he spent long periods at the site on Palomar and at the California Institute of Technology, also living with those who designed and are making the telescope, and set down their oral accounts in lively style. They also checked the book for accuracy He also scoured the country from end to end in search of every root from which the telescope has sprung. Very much of the text consists of personal narrative within quotation marks revealing the actual dealings, the daily give and take, and the differences and compromises of the principals. The book, though largely about people, does not skip the scientific or engineering detail of the huge undertaking. Thus it answers both the personal and astronomical questions which outsiders have often asked in vain. (380 pages, 6¼ by 9¼ inches, 66 illustrations.) -\$3.10 postpaid. -A. G. I.

THE SCIENTIST IN ACTION

By William H. George, Ph.D., Royal Society Research Fellow, Lecturer in Physics, University of Sheffield

ROM this book the thoughtful, studious reader may obtain a picture of the scientific method in some of its most search ing, rigorous aspects and see how the scientist applies it. Not an elementary book. (354 pages, 5½ by 8½ inches.)—\$3.10 postpaid—A. G. I.

COMPOUNDING IN THE ENGLISH LANGUAGE

By Alice Morton Ball

I S it all one word, two separate words, or is it hyphenated? Worst bugbear of writing in our illogical English language is word compounding. If you think that even editors understand it, watch any two of them

fight. Everybody tears out hair, however, about compounding. Here is a book containing a 103-page alphabetical list of nearly 13,000 of the word compounds that cause the most trouble, worked out by an author who has prepared the writing style manual for the U. S. Department of State. When in doubt, you flip it open and there is your answer Also, for those few who want really to learn the principles of com pounding, there is an exhaustive study of the underlying basis of the whole matter (226 pages, 6% by 9½ inches.) - \$2.60 postpaid -A. G. I.

MAN MAKES HIMSELF By V. Gordon Childe

N which a noted British archeologist presents an account of human progress from the Old Stone Age, without inflicting on his readers the technical terminology and pargon of the specialist. He describes three great revolutions in human history—the Neolithic, the urban, and the recent revolution in knowledge. (275 pages, 5 by 8 inches, 11 illustrations.) -\$2.60 postpard .- A G, I

ESSAYS FOR THE STUDY OF STRUC-TURE AND STYLE

By Leo E. A. Saidla

NE of the largest industries in America is that of writing for publication It is said that everybody is writing a novel-or something. This collection of essays with its lengthy discussion of types and style of writing and its discussion of grammatical questions is intended as a guide for these writers. As such it may be highly recommended for slow and careful reading. (717 pages, 5½ by 85% inches.) -\$2.35 post-paid.-F. D. M.

THE PROPERTIES OF GLASS

By George W. Morey, Geophysical Labora tory, Carnegie Institution of Washington

AS Nature patly put it, "an eminently scholarly and exhaustive monograph which is bound to be of immense value to the wide circle who have to do in some way the wide circie wine nave to do in some way or other with glass." Chapters treat re-spectively the history and definition of glass, devitrification, composition, chemical durability, viscosity, annealing, surface ten-sion, heat capacity, heat conductivity, density, coefficient of expansion, elastic properties, strength, thermal endurance hardness. optical properties, electrical conductivity, dielectrics, magnetic properties, constitudefinitely technical. A veritable storehouse of very compact, solid, dependable informastaff of a laboratory which has given much attention to glass since the World War, has been diligently at work since 1924, (561 pages, 6 by 9 inches, 20 illustrations.)—\$12.60 postpaid.—A. G. I.

THE MODELMAKER

Volume 15

A YEAR'S issues of The Modelmaker of particular interest to the hobbyist who has a well-equipped shop and is sometimes at a loss as to what project to start next. P. P.

PROJECTION PRINTING WITH THE PHOTOMETER

By A L. Haynes

EXPOSURE in projection printing is a stumbling block for many amateur photographers. Without correct exposure it becomes impossible to obtain the finest possible quality from the negative. It is bemeters for enlarging have come into rather wide general use in recent years. To guide the photographer in the use of these meters. the author of the present book has prepared what might be termed a manual for this particular phase of photographic endeavor. The chapters deal with exposure meters, paper speed ratings, negative density range, paper exposure scale, and so on. (48 pages, 5% by 8%.) -\$1.10 postpaid.-A. P. P.

ABOUT DETROI FUM

By I. G. Crowther

W HAT petroleum is, where it comes from, where it is obtained, and how it is processed, is the scope of this book written for the motorist, aviator, mechanic, business man, and others, by a technically trained writer who treats the subject neither lightly nor very technically. (181 pages, 5 1/2 by 8 1/2 inches, 24 illustrations.)— \$2.35 postpaid .-- A. G. I.

THIS EARTH OF OURS

By Victor T. Allen, M.S., Ph. D.

EITHER as a readable textbook or a somewhat textbookish popular work, this treatise covers geology, both physical and historical, in a scientific manner, the

We can supply our readers with any of the books reviewed in this department. Prices quoted include domestic postage. Foreign prices are necessarily higher due to increased shipping charges.

SCIENTIFIC AMERICAN 24 West 40th Street New York, N. Y. author being a professional geologist. The treatment is condensed rather than detailed, thus avoiding the chief difficulty which bedevils those who seek to learn geologyconfusion in a morass of detail and terminological jargon. (364 pages, 5 1/2 by 8 1/2 inches, 257 pages.)—\$3.60 postpaid.—

HANDBOOK OF CHEMISTRY AND PHYSICS 23rd Edition

Edited by Charles D. Hodgman

NUMEROUS additions and revisions make this 1939 edition of a familiar reference even more valuable than its predecessors. Important additions are tables of Melting Point Index and Boiling Point Index of Organic Chemicals. The tables of Physical Constants of Inorganic and Metal-Organic Compounds has been thoroughly revised. The page size of the volume has been slightly increased over that of former editions, giving the book better proportions. (2221 pages, 41/2 by 7 inches.) -\$6.10 postpaid -L. B. P.

BACKGROUND TO MODERN SCIENCE Edited by Joseph Needham and Walter Pagel

TEN British writers—Dampier, Ruther ford, Bragg, Aston, Eddington, Ryle, Nuttall, Haldane and other outstanding scientists-lectured at Cambridge University on physics, astronomy, physiology, parasitol ogy, tropical medicine, evolution, and genctics, presenting these subjects historically (mainly, however, reviewing advances during the past 40 years alone). These are the lectures. Informative reading. (243 pages, 51/2 by 8 inches)-\$2.10 postpard -A G. I.

CASEIN AND ITS INDUSTRIAL APPLICATIONS

By Edwin Sutermeister and Frederick L Browne

WHATEVER the chemist wishes to know concerning the chemistry and uses of casein will be found in this very complete study. It discusses and explains in detail for the chemist interested in plasties the background facts in the use of this milk product, its manufacture, testing, analysis, storage, and its use in plastics, glues, paper making, paints, the leather industry, medicine, and other applications Extensive bibliographies and references to articles are given (433 pages, 61/4 by 91/4 inches, numerous illustrations.) —\$6.60 post-paid.—F. D. M.

FASCINATING FAKES IN PHOTOGRAPHY

By Marcel Natkin, D.Sc.

SHADOWGRAMS, smears, screens, bas-relief, photomontage, distortions, infra red-the text runs the whole gamut of photographic tricks that can be accomplished by the average amateur photographer who does his own processing. Many of the effects described are old, in the photographic sense, but they are so well depicted and so thoroughly explained that the book represents genuine value to the serious-minded camera fan. (72 pages, 7 by 11 inches, thoroughly illustrated with a large number of photographs and diagrams.)—32.10 postpaid.—A. P. P.

TELESCOPTICS

A Monthly Department for the Amateur Telescope Maker

Conducted by ALBERT G. INGALLS

LURKING in the rearmost cell of the average amateur telescope maker's brain is the hope that someday he may work up to a full 20" reflector, and a number of telescopes of that size are known to be in the making. The clean-cut Cassegraman re-

Figure 1: 2200 pounds of trim telescope

flector shown in Figures 1, 2, and 3 was built by William Buchele, 2832 Sagamore Road, Toledo, Ohio, who pervously had made two smaller suzes. Modesly, Buchele at first seat that magazine but one small photograph action. The instrument shown by that phototron. The instrument shown by that photograph looked so good that he was invited to put modesty saide and write down the details about this telescope, since these will be of value to other amateurs who plan telescopes of this size.

"Your letter," he replied, "puffed me up a bit and, if I do any bragging, it's your responsibility. I started telescope building about three years ago, using a borrowed copy of the first edition of 'Amateur Telescope Making.'

Figure 2: The Porter split ring

That's when my trouble started, and I haven't been the same since. After making the two smaller instruments I obtained a 21' Pyrex disk weighing 100 pounds and, at the end of about 40 hours' work, I had it roughed out to 1/5. Fine grinding took aix hours,

o //5. Fine grinding took aix nours, polishing nine. This was all done by hand, the 100-pound mirror facedown over a full-sized tool and polisher, and I would not advise any one to attempt this unless he has an elephantine physique. (A. W. Everest also did this—Ed.)

"Figuring was done with small tools, mirror face-up. The correction is within 1.5 percent of a full paraboloid and the figure is smooth and regular, the performance good.

"Both the convex secondary and the diagonal flat are of Pyrex; I turned down 8" diaks to 6½" to gain estra thickness. In correcting the convex I used Hindle's method, and a sphere to figure the flat.

"Hindle's 18-point flotation system (Figure 4) was also used to support the mirror, though I doubled its number of inner edge supports. Figure 4 also shows the outer edge support shoes. The cell is a combination of steel plate and castings, welded, as is the lower part of the tube.

"The lattice-type tube (Figures 1, 2, 3) is bolted to the solid part. Its

Figure 3: Octagon hoops and spider

eight pieces of tubing are of 1½" at suretce, 20 jags wall, old/rolled steel. The 3/16" ite rods and the perforated octagon hoops also are cold/rolled steel, the latter (Figure 3) being made of 16-gage channels. A 1½" washer was brazed into each corner of the octagon and the tubes were then present through these holes and brazed, making a very stiff job regardless of the angle at the pairs of additional tube braces stretched

Figure 4: Cell. Flotation system

over the squared ring at the top of the solid part of the tube. These give added rigidity I can detect no flexure by visual inspection of the mirror reflections.

"For the spiders (Figures 3 and 5) to support the secondary mirrors I used saw-blade steel

"The dechnation axis trunnions (Figures 1, 6, 7) are castings of special material, (cast 170a, nickel steel), as are the four other large parts of the mounting. All were normalized before machining. I made my own patterns

"As I own no lathe or drill press I was forced to have the lathe and similar work done outside.

"The declination bearings are used truck ball bearings (radial thrust, 5" O.D.). They had to be large because the trunnions were to be hollow to allow the reflected rays to

pass through to the eyepieces.
"I placed the declination circle with its shielded light (Figure 6) on the west side. It is divided into half degrees. The index con-

Figure 5: Lower spider. Cell. Prism

Figure 6: Declination circle. Eyepiece

sists of a bright copper wire. On the east side is a reversible slow-motion motor with gearing (Figure 7), mounted on rubber. A small clutch allows this axis also to be moved manually without adjustment or disengagement of gests.

"For the south polar axis I used a radial thrust, self-alining type of bearing (Figure 8). The bearings under the split ring (Figures 2, 3, 9) are used auto parts. The inner race is stationary, while the outer race rotates under the big ring. This gives a fourpoint support, spread over a large part of the ring. Each pair of rollers is pivoted, and this tends to cancel out possible irregularities on the bearing face of the ring.
"The R A. setting circle (Figure 9), is

divided into minutes

Figure 7: Dec. slow motion motor

"The principal gear train for the drive in R.A. has a 1/8 H.P. synchronous motor (Fig-ure 8), mounted on sponge rubber. Slow moure 8), mounted on sponge rubber. Slow mot-tion in R.A. is obtained by a reversible mot-tion are drive. This is mounted on the under-side of the large worm wheel beneath a bousing. The large droubt object in Figure 8, near the worm wheel, is a guard to protect

the gear, also the clothing.

"A 2½" prism, shown dimly beneath its cell ring and above the spider in Figure 5, is used to divert the image to either of the eyepieces at the respective ends of the declina-

pieces at the respective ends of the declina-tion axis, simply by turning the priam cast or west one half turn. Very comfortable ob-serving position is then made possible. "As a finder I use a 6", 1/6.5 reflector with rotatable table (Figure 1). "My observatory (Figure 3), 11) was made by adding 8" to my garage. The telescope rotat on piers (Figure 12), with footings 6" deep. The observatory four is 60% above the deep. The observatory four is 60% above the

118 JOHN STREET NEW YORK

THE BEGINNER'S CORNER

LITTLE ways of doing common operations, devised and used by different workers, are extremely numerous; searcely any two do a pob like, in fact. Ed. C. Rizzo, R.F.D. I, Cold Syring, Ky., cells how he makes laps. In a wooden mold I' wide, 24' nog, 34' deep, lined with wax paper, he pours melted pitch, lets it cool, removes it, prelat he paper off and, in a warm room, cuts the strip into I' squares. Each of the four sides of each aquare as then cut with a re-

entrast curve, the result being a prepared facet, shaped like a four-pointed star. These are attached to the warmed tool with terps. The object of the star-shaped facets is that, after cold-pressing and swelling out, such a shape becomes a square; while a square, as commonly used, tends to become a circle. Whether a lap made of squares is superior to one made of circles is a separate question.)

To make a pitch lap free from bubble holes, Edward Lenard, 4854 N. Austin Ave., Cheago, heats the pitch in a double boiler, stirring it often; then removes the inner receptacle and holds it 6" above a low flame until the pitch is thin enough to pour readily, stirring all the while.

TELESCOPTICS (Continued from preceding page)

garage floor and is 11' square, giving ample room. The housing for the telescope rolls off on a gantry (Figure 10), and is so compact that, when closed, it is scarcely noticeable from the street.

The sidereal clock (Figure 13) was made from an ordinary pendulum clock. For the pendulum slubstituted a longer and compensated pendulum, thus reducing the speed of the hour hand to one revolution per 24 hours. On the dial face is a star map, and stars at the zenith are indicated at all times by the hour hand.

"For the benefit of any faint-hearted apprant for a 20", you may say that I am not an engineer, neither am I a mathematician my school training was very elementary.

"Our local Toledo Astronomy Club is an active one Professor Winslow, of the University of Toledo, is our skipper and we meet monthly at the University."

ETTER from an author:
"In our article, "Some Applications of

Figure 8: South bearing and drive

Figure 9: North bearings, R. A. circle

the Schmidt Principle in Optical Design," by D O Hendrix and myself, in the August number, it was certainly far from our intention to deny credit to anyone to whom credit as due. The meaning of our offending seatence would have been clearer had it been phrased to read · . . . hittle that was not known to Schmidt' instead of 'hittle that is new,'

"Through private sources we know that Schmidt lumself had derived the fundamental equation and had considered various

SURVEYING the durability of aluminized and chrome-aluminized mirrors, in

Figure 12: The two massive piers

Figure 13: Buchele, Sidereal clock

the June, 1939, Astrophysical Journal, Robley C Williams of the University of Michigan, after questionnairing 16 observatories, states in an 11-page article that "the most probable useful life of a coating of either of the films is from 21/2 to upward of five years, depending upon the excellence of the conting, its care, and the degree to which it is subjected to condensed moisture and dirt particles.

In the July number of the same journala professional astronomer's journal than which there certainly is no whicher-occurs the statement that the new Skilling and Richardson "Astronomy", reviewed in Scientific American for August, is "the best single book available for teaching a large amount of astronomy to the uninitiated student," in flattering agreement with our own review.

Dave Woodbury, a T.N. whose book, "The Class Giant of Palomar," on the 200", is reviewed elsewhere in the present number and who lives in Ogunquit, Maine, is now lecturetouring here and there among clubs of amateurs, using a heavy assortment of lantern slides. He has also lectured before Rotary Clubs and even Women's Clubs, but here he tempera his technicalities to the shorn lambs.

WHO can excel the record of C. P. W Dayton, Lyford, Tex., for telescope pier? His is 2200' deep! Because his locality is underlain by a 40' stratum of quicksand, trains moving within five miles of the telescope caused serious shimmying. An 8' concrete pier made it worse. He felt whipped. Then came an oil company, drilled a 9000' well on his land. Dry hole. But it wasn't a total loss, for Dayton found that, when he set his telescope on the 2200' of 10%" casing the drillers had left cemented in the bowels of the earth, the telescope had the stability of Palomar. Seismoscope becomes telescope.

TRADE MARKS AND UNFAIR COMPETITION

By ORSON D. MUNN

A TRADE MARK is an intangible asset of a business, yet its actual value may grow so large that it becomes the very foundation on which depends the whole structure of the business. Because of this fact, every business man should have available such information on trade marks as will enable him to judge with a fair degree of accuracy the desirability of any mark which he may be considering.

Here, in one handy volume, written in non-legal terms, is a simple yet comprehensive interpretation of the Federal statutes and the body of common law relating to trade marks and unfair competition.

THE AMERICAN WAY IN PRABASACY, by George D. Beal, is a nine-page reptint of an article that deals largely with the acce exercised by drug manufacturers in the production of materials which find their way into the home through doctors' pre-scriptions. It is illustrated with a number of photographs that show various steeps in manufacture. Mellon Institute, Pittsburgh, Pennsylvania,—Gratis.

LEGAL HIGH-LIGHTS

Patent, Trade Mark, and Related Legal Proceedings That May Have a Direct Effect on Your Business

By ORSON D. MUNN, Litt.B., L.L.B., Sc.D.

New York Bar Editor, Scientific American

CRAWLING BABY

THE representation of a crawling baby, then used as a trade mark, is deceputed similar to a representation of another, even though different, crawling baby, according to a recent decision of the Court of Customs and Patent Appeals.

A prominent manufacturer of babies' rubber pants sought to obtain the registration of a trade mark featuring the picture of a crawling baby and in which a second baby was pictured in stooping position holding and stretching the garment of the first haby. The registration of the trade mark was opposed by another manufacturer of babies' pants who owned a registration featuring a baby in crawling position. The Court recognized that the two marks were different in detail but held that the dommant feature in each mark was the representation of a crawling baby and that unless the marks were placed side to side there was a danger of confusion. Under the circumstances the opposition was sustained and registration of the first mentioned trade mark was refused.

CHINESE-AMERICAN

FEW Americans realize that the United States maintains a court in China where certain of the rights of American citizens and of American corporations in China are determined.

One of the recent cases decided by the United States Court for China involved the well-known American trade mark Coca Cola. Stut was brought by the owner of the trade mark Coca Cola against a competing manuacture selling a somewhat similar product under the name of Eddie-Kola. The Court Court of the Cou

In the Court's opinion it also appeared that the name Coca Cola was registered as a trade mark in China in Chinese characters and the Court pointed out that the defendant had voluntarily agreed to discontinue the use of the registered Chinese trade water.

SIPHON CAPSULE

THE configuration of an article is not proper subject matter for the registration of a trade mark, where the configuration serves a useful purpose. This is illustrated by a decision of the Court of Customs and Patent Appeals involving a capsule containing compressed carbon district to be used for carbonating water in recharge-this root, subplement The capsule consisted to the soft of the contract of the contrac

of a tubular bulb having a perspheral grows on one side of the central portion. The manufacturer of the capsule contended that the grows constituted a trade mark and he attempted to register it in the United States Patent Office. The Commissioner of Patents demed the registration on the grounds that the grows esercied a useful purpose and the decision of the Commissioner was affirmed by the Court.

In reaching its decision the Court referred to a mechanical patent disclosing a capsule of this character, in which it stated the groove served to hold the capsule in proper position in the holder provided on the soda bottle. Under the circumstances the court stated.

"We are unable to escape the conclusion that the groove as an entity possessed utility and, for that reason, under the authorities, is not a proper subject for registration as a trade mark."

CLEOPATRA

THE personal habits of the famous THE personal names of the American Tegyptian queen, Cleopatra, were discussed in a recent suit for patent infringe ment. The suit was filed by the owner of a patent for a cleansing cream containing milk and it was charged that the defendant had infringed the patent by making similar cleansing cream. One of the defenses raised was that milk served no useful purpose in the cleansing cream and that in order to be patentable an invention must be useful rather than frivolous. In answer to this defense the patentee contended that milk ap plied to the skin tended to whiten it and referred to the legend of Cleopatra taking daily milk baths claiming that this made her "the only white woman in a darkskinned race.

The Court, however, rejected the legend as a myth, held that milk did not have a whitening effect on the skin, and declared the patent invalid. In this connection the court sated:

court stated:
"But it is well known that milk does not
have a whitening effect; that the story of
Cleopatra and her milk baths is a pure

MEIN KAMPF

THE rediktoren book, "Mein Kangi."
by Adolf Hilder, is at present involved
in the Adolf Hilder, is at present involved
in the Adolf Hilder of the Federal Courts.
The publisher of an authorized edition of
the book owned the United States copyrights
thereon and bought suit against the publisher of an unauthorized edition. Pending
the final determination of the suit the Court
was asked to grant a preliminary injunction
tratraining any further distribution of the

unauthorized version. The injunction was opposed by the publisher of the unauthorized version on the grounds that at the time that the copyright was obtained Adolf Hutler was not a citizen of any country but, on the contrary, was stateless and on the further grounds that Adolf Hitler had not formally assigned his copyright.

The trial court denied the injunction but. The trial court denied the front Court of Appeals which can the far that the United States Copyright Law heads the that Builted States Copyright to both aliens and eliticates and elitic to overteel to be the tright of copyraph to both aliens and elitic seas and that no returction were placed upon a person who was stateless. The only returnicion of limitation was placed upon an alien who was a citizen of another court. Under those circumstances it is necessary that the alien author cither be donied in the United States or that he be the citizen of a country which extends re-ciprocal privilegas to American citizens.

With regard to the title to the copyright the Court of Appeals held that Adolf Huler had delivered the manuscript to the publisher's predecessor in title and that the delivery of a manuscript under such ercumstances constituted a transfer of the legal title to the manuscript. The injunction was accordingly granted pending the outcome of the trial

CO-PENDING

WIAT is the effect of an earlier patent, which discloses but does not claim as invention which discloses between the control claim as invention. The control claim is the same patenter which does claim the invention? This question arose in a recent sait involving a patent for a method of forming rubber tires. It was contended by the defendant that the patent in suit was invalid because the same invention was disclosed in an earlier patent granted to the same patentee. The Court rejected this contention, however, pointing out that the applications for the two patents were opending in the Patent Office and correlanging the Patent Office and to form part of the price art and office the validity of the beatent, and affect the validity of the beatent, and

CONTEMPT

O RDINARILY, a person violating an injunction restraining the infringement merely subject to a fine which is latended to indemnify the patentee. Thus is illustrated by a recent suit involving a patent for a frozen confection. On consent of the defendant and injunction had been entered restraining the defendant from infringing patent contended that the defendant had violated the injunction by continuing to sell infringing articles and instituted proceedings to have the defendant had violated the injunction by continuing to cost in the patent contended that the defendant had violated the injunction by continuing to cost in the patent patent contended that the defendant had violated the injunction by continuing to court.

The trial court found that the defendant had violated the injunction, adjudged he was guilty of contempt of court, and committed him to jail. An appeal was taken to the Court of Appeals and the decision of the trial court was reversed. The Court of Appeals pointed out that the contempt proceedings were prosecuted by the attorner for the particular trial accordingly were procedured to the proceedings were processed to the proceedings were proceedings were proceedings with accordingly were guided from criminal contempt, In civil contempt proceedings the court held that a party could not be committed to isli.

Is Your Name Here?

BELOW are the names of some of the most distinguished American families. Our research staff has, over a period of years, completed manuscript histories of each of these families. If your surname is listed, you should have your manuscript, We believe you will find it not only of keen interest, but a source of pride and satisfaction for yourself and your kinsmen.

THESE FAMILY HISTORIES ONLY \$2.00 EACH

Henry Henry

Each manuscript is a GENEALOGICAL and Harm HISTORICAL study of the family from earliest the control of the co

illustrated, informative publication prepared by the Bureau II your order arrives promptly we will also include, at no extra cost, our specially designed Ancestry Chart (regularly 35 cents each) It measures

cally designed Ancestry Chart (regularly 35 cents each). It measures 17 by 22 inches and contains spaces in which to record the names of your auxiestors in all house for eight generations of the couple, which are composed to the couple, with \$3.00 (no other charge), will bring your manuscript by return mail Satisfaction is assured by our unconditional money-back guaranty. Any two manuscripts may be had for \$3.75, any three for \$5.00. Send for your index MERIAR EMBRAUL, Dept., 2411, 1101 F Street, Washington, D C

Automaton Salesmen..... with Life-Like Action, are Finding Wide Use As Advertising Novelties

50 Years Ago in . . .

(Condensed From Issues of November, 1889)

CANAL—"The Nicaragua Canal Company, after exhaustwe prelumnary surveys, bormap, etc., and the preparation of complete maps and profiles, has now started in on actual work. The total length of the route, as finally located, as 170 unless, of this length, 121 unless as free navagation of Lake Nicaragua and the San Juan Rwer, requiring only a little dredging and improvement; 22 unless is free navigation of basins formed by the Booding of two valleys, when the start of the start of the start of the start of the start to on the sasten, three on the western division.

MILITARY BICYCLES—"The art of war is now borrowing from applied science all the resources that are at the latter's disposal, atther is nothing up to velocipedism that is not contributing to the service of the army ... The illustration shows a phase in the use of the military bicycle as practiced in England, the illustration of

which we borrow from the Illustrated London Neur. A small body of cyclast, at an in number (two sections and a half-section), with officers and bugler, marching in usual order of half-sections—that is, by 'twos'—are stacked by cavalry. At the word of command, 'listit' Prepare for cavalry! Form square!' each man dismounts; and the respective second half-section move up alongside their first half-section, so as to form a line of four men in front and rear, with a half-section of two men between them. The rifles are lifted out of their clips as the machines are . . . placed upside down . . . Lastly, each man, as he lies or kneels down behand his machine, sets his wheels splinning round with a touch of his finger. For the contrast contrast the contrast contrast

AUSTRIAN 'PHONE—"Long-distance telephonic communication was opened on October 1 in Austria between Vienns and Prague, a distance of 220 miles. Every subscriber in Vienns can now communicate with Prague, and every word can be perfectly understood and the voice recognized."

EFFICIENCY.—"After a steer goes into a slaughter house nowadays, the only thing that is wasted is his dying breath, and if it were possible to find some use for that, no doubt it would be caught and preserved. Nothing else is wasted, from the tip of the tongue to the brush on the end of the tail."

BRIDGE—"The Illinois Central opened in \$2.50,000 bridge across the Ohn River at Cairo on the 25th th. . . . The bridge proper is 2 miles long, and the approaches 4 miles long. The bridge is 58 feet above low water. The piers are in pseumatic caisons, and are sunk 50 feet below the bed of the river . . At this depth below the river bed no foundation was reached, and ty as impossible to his the piers turner. They were consequently packed with sand, and the immense bridge is really vanished by the frettion of the seand on the sides of the piers."

ARMOR PIERCING—"At the Paris exhibition the firm of Holtzer show a shell which pierced a steel plate 10 inches thick and landed entire without a flaw 800 yards, or nearly half a mile, distant from the target. Only the point of the shell was slightly distorted."

AFRIAL PHOTOGRAPHY—"A new use has been found for the carrier pigeon in Russia—carrying negatives taken in a balloon to the photographer's dark room."

IRRIGATION -"A large force of men is at work constructing an irrigation canal fourteen miles long, to irrigate a tract of 50,000 acres in Fresno County, California. The canal will be of feet wide and 6 feet deep. This tract of land will be cut up into 20 acre farms and placed on the market."

AGCENTINA—"The Argentine Republic as growing at a really remarkable rate, Buenos Arres, its capital, having a population of nearly half a million. In 1888 it had foreign commerce of 2280,550,000, ob with \$112,410,000 represented imports, including \$44,000,000 coin, and \$108,280,000 exports. Its demands for supplies for the construction of railroads, which, in 1887, were only \$3,500,000, rose in 1888 to \$13,500,000. Of agricultural products, it exported in 1887 \$21,257,230. against only \$8,343,358 the persons

WELDING—"The Thomson Electric Welding Company, at their Lynn works, have . . . been able to weld wire cable 15/16 inches in diameter for a cable to be used on a cable railroad, aboving greater efficiency than was thought possible in doing this very difficult work. Although the strength of joints obtained by splicing was about thirty percent that of the original cable, yet it was found from tests made at the Watertown areanal of electric welds made of this cable that eighty-seven percent of the efficiency of the rope intelf had been obtained in these welds."

JAPAN—"Let us take a glance in the direction of Japan. Here we are assumished by the wonderful progress she has made since Perry's expedition, and especially during the last twenty years. Her power and prosperity are steadily increasing. The recent adoption by Japan of a constitutional form of government was a great stavance in the path of progress, and marks a turning point in her history. Japan is destined to be one of the great states of the future."

PULLMAN—"The . . Pullman's Palace Car Company . . . is now supplying with sleepers 117,856 miles of the 160,000 miles of railroad in the United States . . . The total number of employes of the company is 11,053, and these employes received in wages nearly \$6,000,000 during the neat year."

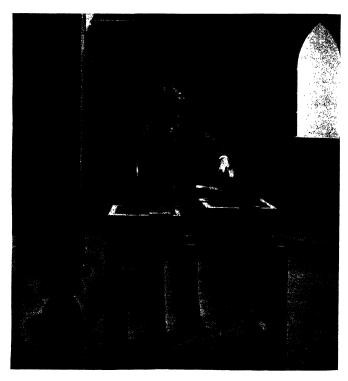

AND NOW FOR THE FUTURE

LIGHTNING IS TRAPPED AND DISSECTED

SCIENTISTS have almost literally snatched bolts of lightning from the skies with the device pictured above. Installed atop the 24-story Cathedral of Learning in Pitsburgh, by Westinghouse engineers, it is called a fullerhonograph because it measures both time and amperage of a lightning stroke, broken mot unly but for analysis. Already it has captured one bolt lasting 1/60 of a second and having a maximum current of 21,000 amperes. Its heart is a slotted wheel—filled with projecting laminated magnet steel films—which is rotated through two coils which earry the total surge of lightning that passes asfely through a new type of arrester Because of the speed of the wheel and the number of fins, the device can make a recording every 40 millionths of a second. It will give valuable assistance to engineers perfecting power line protectine equipment.

No sinecure is a motor expedition through the Sahara. Though the great desert (Sahara means "desert") is very largely rock and not the traditional sand, enough of it really is sand to provide a motorist's nightmare. Note steel channels under wheels

A Lost World Refound

The several hundred thousand years man of the lower and moddle Paleo-think age roamed over the tree-covered expanse of what is now the Sahara, trapping game and chipping stone implements of fixed, almost unchangeable, design. Then the rainfall dwindled, probably because of the final recession of the ice-cap over northern Europe. The people were forced to accommodate themselves to the changed conditions.

We know nothing of the details of human movements during this enormous period, and very little even of the out line. At some unknown date, many thousands of years ago, the people of the North African plains began to domesticate cattle and to pasture herds in the thinning vegetation. Later on they learned to eat cereals as well as meat, and ground some sort of wild grain. These changes appear to be connected in some way with the development of the Noslithic culture with its bewildering variety of stone implement types.

Then, very recently, between 5000 and 10,000 years a.C., there came a further edge of desiccation. The great plains attage of desiccation. The great plains dried up and were abandoned. Mas migrated to the highlands bordering the desert where more rain still fell, and to the banks of the river Nile where they could grow gain without the need of any zain at all. Here began that settled life which, stumulated by contacts with

On a High Plateau Far in the Sahara's Isolation, Archeologists Have Discovered Evidence of Early Man's Culture... A Land Formerly Wet and Fertile

By MAJOR R. A. BAGNOLD

A sketch-map showing the route of the expedition from the Nile 500 miles to the west into deserts so uninhabited that the trip seems like a visit to a strange planet

more advanced communities in the east and northeast, very soon gave birth to the great civilization of ancient Egypt. Archeologists have concentrated largely on this last settled phase, but no funds have been available for a systematic examination of the old motherlands, chiefly because the Libyan Desert is so vast and waterless that, until recently, prolonged and detailed work far away in the interior was thought impossible.

This areat desert, roughly the size and shape of India, is indeed overwhelming in its lifeless silence and its sandy desolation. No vegetation of any sort exists except in the oasea, for even a sprinkling of rain now falls on any one place less often than once in ten years. Seeds carried by the wind may germinate after a rare shower, but they quickly die in a ground whence all the fertile humus has long ago been blown away. The oases lie at the bottoms of deep and wide depressions, often surrounded by cliffs. They have been ex-

cavated by the wind down to the level of the underlying artesian water which originates in rainfall far away on lands outside the desert region. The oasenearest to the Nile and to the Mediterranean are large, and support a permanent population, but the majority consist merely of a few date palms, some swamp grass and reeds, all struggling to live in salt-encrusted soil. Some are mere water-holes which become filled with sand and have to be dug out afresh by travelers needing water.

But even the water-holes are from 200 to 400 miles apart. Between them stretch bare rock plateaus, dead-flat sheets of sand a single one of which may be 5000 square miles in area, and ranges of giant sand dunes running straight and continuous for hundreds of miles One or two ancient and now disused caravan routes cross the corners of the desert from one oasis to the next, but it is unlikely that any Bedouin tribes have roamed over such a landscape since the final drought overtook it thousands of years ago. For, without grazing on the way, no camel can do a journey of more than 350 miles, or 15 days, without water; and half such a journey is an

AN expedition by car into the interior resembles a voyage of discovery at sea. With three specially equipped light vehicles a party of six can be self-contained as regards motor fuel for 1400 miles, and can remain for long periods out of reach of water. Though tire marks persist in some places for 25 years and longer, there are no regular beaten tracks; and for fear of losing their way travelers prefer to steer their own route, keeping a dead-reckoning course by day, and checking their position by the stars when camped for the night. Water is sealed in four-gallon cans, and may be kept in depots for many years without ill effects. One quickly becomes accustomed to a daily water ration of only four pints. Kit and equipment are out to the bare minimum to save weight for essential supplies. No tents are carried; one sleeps well on the open sand, without fear of attack by man or beast, by insect or microbe. The air is keen and envigorating in winter. Yet great caution and forethought are necessary. A party stranded beyond walking distance of an occupied oasis can have no hope of surveyal.

Within the last 15 years many such expeditions, led at first by the great Egyptian explorer Prince Kemal el Din. and later by the writer and others, have penetrated westward from the Nile beyond the frontiers of Egypt, even as far as the Thibesti Mountains 900 miles across the desert. The object, being largely geographical, great distances-4000 to 7000 miles-were covered rapidly on each occasion. As a result, the curtain of mystery and legend that had hung over the country since ancient times has been lifted All the major geographical features, including the existing oases and the low-lying areas where water might be found near the surface, have now been mapped, albeit rather hastily. Some idea, too, of the immense wealth of archeological material had been gained

In 1938 a new experiment was tried out successfully. A party of nine men,

Cave paintings in red, white, yellow. Age unknown--probably between 4000 and 6000 years, yet unused pigments lay on the ground below, just as the artist had once left them

Below: Top of the Gilf plateau, showing some of the cliffs, 1000 feet in height, which surround this odd, remote world set atop of another odd remote world in the desert's featness.

including the Egyptologist O. H. Myers and three native diggers, was enabled, through the generosity of the late Sir Robert Mond, to spend two months in a detailed examination of one promising area lying 160 miles from the nearest well.

In the very center of the desert, and at the extreme south-west corner of Egypt, lies the solitary mountain of Uweinat. Northeast of it, pust visible on the horizon, the level of the yellow, featureless plain rises abruptly by a continuous 1000-foot wall of cliffs, for all the world like some black forbidding coastline, to the isolated plateau of the Galf K-bly.

The general outline of the plateau had already been mapped roughly from below, and its cliffs had been traced 150 miles northward till they disappeared under the mighty billows of the Sand Sea dunes, but neither the deep winding creeks and fiords which were seen to penetrate the outer wall, nor the upper surface beyond the flat monotonous skylme of the cliffs, had ever been explored. Though now completely waterless, it seemed most probable that the extra rainfall induced by these highlands would have continued to support a remnant of the old population long after the plains below were dead. If so, much interesting archeological material

was likely to be found. Our hopes were justified to an almost embarrassing ex-

tent The expedition was indeed a journey into the past. For in this country time stands still. Nothing changes; nothing has been disturbed. The Neolithic grinder yet lies in the hollow of the stone quern, just as some Stone-Age woman left it ages ago. The very hearths are there, strewn about with beads, trinkets, and household tools. The ashes look no older than those of a modern Bedouin encampment. On the walls of caves under the great cliffs there still survive the vivid paintings of the ancient people themselves. One sees folk clad in strange primitive garments engaged in lively dances, and tending cattle that would now find no single blade of grass. In the same caves, and on the rocks nearby are older paintings and cruder incised drawings of far earlier peoples shown hunting beasts that have long since disappeared.

This timelessness constitutes a difficulty, for one never knows into what age one has by chance arrived. Our first camp beneath the cliffs, sited among ramins of a Noellthie folk whose date was guessed as about 5000 n.c., was found to border also on the dim past of 200,000 years age; for it lay on the edge of a much larger settlement of Acheulean man whose distinctive and well-known Paleolithic implements covered an area of more than a square mile of country and mingled with those of the later age.

For the first three weeks, while the archeologists were at work on these sites, two of us with a single car threaded our way along the bottoms of each, in turn,

A dry valley penetrating into the Gilf plateau. A car, seen as a dot behind two rocks justing out of the sand within the circle, gives the scale of grandeur

Left: On top of the Gilf plateau today are tracks made thousands of years ago. In all this time there has been nothing to change them: an almost wholly static world

of the long gorges that pierce the Gilf plateau, mapping as we went. Always the same towering cliffs hemmed us in. Counting all the branches and ramifications of the valleys, the total cliff frontage must exceed 2000 miles, yet nowhere apparently could a route be found by which a car could be driven to the top; and we despaired of ever being able to survey the "Lost World" above. At last, however, a very tall sand drift was discovered whose upper slope spanned the final hundred feet of overhanging rock. After four abortive attempts to charge up it with our car unloaded, the skyline suddenly fell away: we were upon a rock surface even flatter than the plains below.

To our astonishment a row of cairns already marked the spot, and well-beaten tracks led away into the mirage over the unknown table land. We had unwittingly hit upon a pass probably last used by the Stone Age people when the lifeless yellow plain below was green.

D URING the days spent on its top the cilifornia upon us the complete illusion of living upon a cilif-girt island rising from mid-ocean: the endless succession of headlands, all of even height, the cliffs beneath them falling shear from the flatness of the landscape without prelimizery drainage alopes, the

limitless plains 1000 feet below, so far down that their blurred yellow features fade away into the shimmering hase. Even more striking was the steady booming of the wind that sweeps continually over the plateau and swirls away into space over the edge of the cliffs: nothing could better imitate the roar of breakers on a distant beach.

There grew also an uncanny fancy that the ancient people were still about -that there was nothing between them and us. The place has the utter remoteness of another world. One felt suspended high above the desert below, itself many hundreds of miles from the nearest habitation. The surface is a harsh barrenness of broken rock. Yet a network of paths cross and re-cross it. Lines of stones are laid out in curious patterns, as if by children playing at forts. Implements and stone flakes are everywhere; near the cliff edges the ground is literally covered with them, some blackened by the sun, but others so fresh they might be yesterday's chippings. We expected at any moment to witness the return of their makers, uncouth figures clambering up the skyline of the cliffs, hammer-stone in hand. to resume their eternal rock-breaking.

Life during those two months was by no means uneventful in other respects. Violent sandstorms broke upon our lit-

tle camp, which was once nearly buried, in our absence, by the shifting of a nearby dune. On three occasions we heard the famous "song of the sands, each time in the stillness of the night. Without warning the whole ground reverberated for many minutes with a loud and low-pitched hooting that issued from the surrounding dunes. Operating 200 miles away from the rest of the party two of us became stranded owing to a serious accident to our one car, and had to walk 25 miles to a pre-arranged rendezvous with the others, carrying all our supplies of water and food on our backs. But, to the writer at least, the most lasting memory of the expedition doubtless will be a trivial incident which happened in a cave in which we had taken shelter for the night from the cold wind. The beam of a torch fell on an artificial rock ledge. On the ledge lay a solitary stone knife left behind by the last occupant untold centuries ago, just as we ourselves would em; our pockets before going to bed.

[The "booming of the wind," described by the author, is due to myriads of acolian whispers—slight sounds in the vortexes in the lee of minor obstructions but the "song of the sands," also mentioned, is not clearly understood by

scientists.—Ed.]
This expedition has proved the possibility of archeological work under the worst desert conditions. Years of patient work will be required before the complex story of man's wanderings in North Africa can be disentangled. It is to be hoped, however, that the evidence so marvelously preserved can be collected while it is still intact, before the adventurous sight-seer has unthinkingly rifled the sites of their most important implements, and before the artist, intent on copying the precious wall paintings in the caves, has trampled on the contemporary floor relics which alone can correlate the paintings with the implement sites outside.

RIVER REBUILT TO CURB FLOODS

Los Angeles River during the flood of March 1938. Abrupt curves, where river breached and caused damage, have been straightened

NDER conditions existing until recently, according to Major Theodore Wyman, Jr., U. S. Engineer Department district engineer, a great flood would practically cut off access to the city of Los Angeles, with its nonulation of 1,500,000. In fact, Major Wyman

pointed out that the wide plain on which Los Angeles is situated is under a more dangerous flood menace than any similar region in the United States.

Accordingly, Army engineers and the Los Angeles County Flood Control District are literally rebuilding the Los Angeles River, a stream which, in 40 miles, experiences a fall equal to that of the Mississippi River between Omaha, Nebraska, and the Gulf of Mexico. Rebuilding the river is part of a broader flood control

plan. Already Los Angeles County has spent \$60,000,000 in building parts of the protective works. Present plans call for an expenditure of \$70,000,000 more. But amounts of money to be spent give no idea of the engineering difficulties and problems involved; not only must flood waters and debris of the discharging flood be curbed, but also as much water as possible must be conserved to replenish ground water storage. The life of much of southern California depends upon such stored waters

Work to date, recommended by the Board of Engineers for Rivers and Harbors and approved by the Chief of Engineers, has been done at points where floor danger was most imminent. In foothill areas, some 600 basins and Engineers are Protecting Los Angeles and Surrounding Area . . . Flood Control and Water Conservation Dual Aim

By ANDREW R. BOONE

dams have been constructed to trap water-borne debris and to check water traveling at high velocities; channels

crete channels The major drainage system of this area is formed by two main channelsthe Los Angeles and San Gabriel Rivers. These are interconnected by the Rio Hondo, through which water from the

have been constructed to control the water flowing from these basins Below the foothills and on the coastal plain. various channels have been enlarged, straightened, and provided with bank protection, or enclosed within reinforced con-

upper San Gabriel flows into the Los Angeles River. In general, these rivers have their headwaters in the San Gabriel Mountains, a portion of the Sierra Madre

Most important of the streams, insofar as their rampages may affect concentrated population, is the Los Angeles River. This stream, 70 miles in length. may be bone dry in summer, and then carry water at the rate of 90,000 cubic feet a second through downtown Los Angeles during a winter flood. Hence. to save congested areas within the city proper, as well as outlying areas, the improvements proposed for the river include construction of a leveed channel from its headwaters to the ocean; construction of three flood-control basins: and channel improvement in two washes which empty into the river, as well as on other tributaries.

Most dramatic, perhaps, are the straightening, widening, and deepening of the river within the congested district

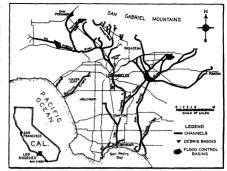

Left: Placing steel for buttresses used where vertical channel walls merge gradually into sloping walls

Below: Construction in a congest area, with mountain on one side and railroad yards on the other. channel bottom is being paved here

of Los Angeles. Were you to follow the river from its headwaters (see map) you would first come upon an excavated trapezoidal earth channel for a distance of some eight miles; a gunite trapezoidal channel for 5.3 miles above the junction with Tujunga Wash: a concrete and rock paved channel from this wash 7.6 miles to the junction with Verdugo Wash; and a trapezoidal channel with concrete slab or grouted rock bank protection from about this point 6.8 miles to Davton Avenue, with a special concrete section at the inlet of Verdugo Wash. From Dayton Avenue, the channel traverses the congested business and industrial districts for a distance of five miles. Due to limited rights-of-way available and the proximity of main-line railroads on each side, channel dimensions vary throughout the reach. At some points the channel must be deepened, with consequent faster stream flow. From Soto Street to the sea, several methods of construction apply.

wide with side walls 31 feet high, has been provided. Here, velocity is figured for 83,700 cubic feet a second at about 14 miles an hour.

From many points of view, re-building this fractious stream presents engineering novelty. It is only part of a larger program, however: that of saving both life and property over a wide area of southern California and conserving water that agriculture and industry may not suffer. How well the engineers have built only time and flood can tell.

Left: Settling basin at junction of Verdugo Wash and Los Angeles River, showing baffles (foreground)

Below: Buffle walls built across the channel (in right foreground) are to guard against over-scouring

Graceful transitions are made from melimed to vertical walls. In some sections rip-rap may be hand-placed and grouted, concrete being poured down a spout from a paving machine or delivered via boom and bucket. Elsewhere, reinforced concrete slabs may be placed over derrick stone. Again, a transition escition of reinforced concrete slab but treases merges a trapezoidal section, which a vertical wall section, the latter perhaps of cantilever type which is poured in place.

During flood, it is anticipated that velocities through the downtown area will vary from 10 to 24 miles an hour, speed depending upon the section. For example, for a distance of 1900 feet, a rectangular concrete channel, 177 feet

TERMITES OF THE SEA

TRESTLE crashed, dumping a train into San Francisco Bay. Nearby, a ferry slip mysteriously collapsed. At Provincetown, Massachusetts, a fish pier fell into the Atlantic. A bridge keeper's house, supported on piling driven into a river that feeds Boston Harbor, tumbled into the water. All of these mishaps, and thousands of others like them all over the world, were caused by the tireless burrowings of the Teredo, a marine creature so fragile that it all but defies human handling, yet sturdy and persistent enough to honeycomb the toughest woods-teak, mahogany, eucalyptus.

Few of man's tiny enemies wreak such destruction. In three years, the Teredo did \$5,000,000 worth of damage to Boston Harbor; in a four-year invasion of San Francisco Bay, \$25,000,000. It now seems ready to attack the richest, biggest harbor of all—New York.

This swift, secret destroyer has been with us for centures. The ancient Greeks and Romans called it the ship-worm, and sheathed their fighting vessels with copper against its ravages. Only recently have we discovered exactly what it is, how it lives, and how its dependence on the predations in our harbors can be prevented. The world's battle against it extension that the center in one cheerful, unorthodox man, William F. Clapp, and in the scientific campaign waged by his selfies, happy-go-lucky laboratory in an old barn in Durbury, Massachusetts.

The true research worker is often marked almost in infancy. By the time he was 12, young Clapp had an excellent collection of msects, makes, and shells. In his freshman year at Harvard, he had no difficulty getting a job as assistant curator of mollusca. Taking only those courses which interested him made getting a degree difficult—he has none to this day—but quickly won him a permanent appointment to the faculty. He taught at both Harvard and Massachusetts Institute of Technology, and laid the groundwork for the new science of biological engineering.

FOR 15 years he was chiefly engaged in classifying specimens, makindose minute examinations which determine whether a given snail or shellfish belongs to a new species or is only a variety of a species already recognized. He might have remained permanently absorbed in this specialized corner of pure science but for a queer piece of wood that was sent to him in 1920.

This specimen of timber came from a

Worm-Like Mollusk... Honeycombs Piling, Timbers... Biologist Studies It In Barn Laboratory...
Records Its Depredations... Advises on Protection

By J. D. RATCLIFF

dock in San Francisco, all but eaten away by some marine "termite." What had destroyed it? Those who had sent it wanted to know. After careful study, Clapp named the shipworm of history, Teredo Nayads, as the culprit.

Impressed by his diagnosis and his report, a Committee of the National Research Council, formed to investigate the

A pile from Chelsea, Massachusetts, showing the result of a heavy marineborer attack, especially at mud line

damage done by marine borers along the United States coastline, invited Clapp to join them as a biologist. Confronted by an intriguing practical problem, Clapp embarked on a piece of research which has taken him far beyond his early years of classification and nomenclature in universities and made him a uniquely unserful specialist to whom great industrial companies come crying "Biologist, bloogist, aver my dock."

Some people think of research as a peaseful, well-rewarded profession conducted by untroubled men in long white costs working in laboratories supported by great foundations. Nothing could less resemble the conductions under which William F. Clasp has waged his way on

the Teredo. His laboratories have been as makeshift and fugitive as a Kentucky moonshiner's still. One laboratory was a total loss because the harbor over which it was built suddenly was polluted by the seepage from oil tankers Then he set up shop in a 60-year-old schooner, donated by friends, which he fitted up as a marine laboratory, and which the Coast Guard obligingly towed from place to place. When the decrepit schooner sank, he had to begin again Now the general staff, and the intelligence service with its priceless records of the doings of the enemy, Teredo, in all parts of the world, are housed in an old barn. There, in an atmosphere of casual simplicity and hard work, Clapp and his staff of seven young technicians -at \$25 a week-are learning all there is to know about the immense destructiveness of minute animals.

LIFE in the old barn is insecure, hand to mouth, enthusiastically singleminded. Marine borers are discussed with the same vehemence that other people discuss the New Deal-and sometimes that vehemence is all that keeps them warm. One winter the laboratory was so cold that a railroad official found the workers wearing their overcoats. As the railroad company had benefited from their research, it shortly sent a check for \$1000-enough for a new heating system. Equipment is often lacking, but if needed badly enough it somehow appears, and a compound microscope, or a filing cabinet, or a pressure heater for experimenting with wood preservatives. miraculously falls from heaven.

Invaluable specimens and records are stored in this pittilly infammable barn Here is a collection of marine borers larger than those of all the mueums of the world put together. Here are individual records of a million individual wooden piles, detailed data on the fluctuating activity of borers in hundreds of harbors. Everything known about the Teredo—as well as fungl, rats, ternites-rusts, and other destroyers of structural deal has become known since William F. Clapp entered this almost unexplored

field just a bit more than 20 years ago. The Teredo, which looks like a grey-ish-white worm, is actually a mollundar a relative of the oyster and the clam. This tribe, together with the crustaces (the family of lobsters, crabs, and shrump) bosts thousands of species whose differences would interest only the biologist, but whose one common point is of painful concern to owners of property on salt water: they chew their way mot wooden pilling, leaving no visible entrance on the outside, and tunnel until, very often, it unexpectedly collapses.

A pile which seems quite solid may contain tens of thousands of borers, some as much as six feet long. Bored beams and piles which look virginally sound may be broken over one's

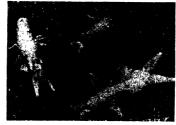

may be Droken over one; knee. The Teredo can ruin a costly wharf in as little as two months. It also destroys the planking of boats, and has been known to eat through hawsers, cutting yachts adrift.

Teredos are launched into the order as free-ewimning larve; minute in size but immensely promising. Sea currents will deposit some of them on rocks, some on the mud bottom, and some on wooden pling. Wherever they land, they instantly answer some urge of instinct and start burrowing. Right: Stages in the life of Limnoria, a marine borer. A shows a grown female; B, very young specimen (note dark eye); C, Young; D, Immature

Directly below: Still another marine borer, Chelura terebrans, photographed enlarged

Bottom: Teredo Navalis, which sometimes attains a length of six feet. P,P are the pallets through which food enters and waste is thrown out. S,S are its grinding shells

thick and hard that it cannot be broken by the strongest fingers.

One burrow may approach those belonging to other creatures of its kind, but they never merge. Perhaps only a lime-coated membrane of well separate tunnels but each will maintain its discreet identity. The Teredo may bore directly through a timber but it will never bore through to the open on the side opposite its entrance.

When the constant rocking motion of its head has worn out one set of den-

ticles—or teeth—Teredo sprouts another. As many as a hundred rows of these microscopic teeth have been found in one of these creatures. Delicate as they are, no structural wood hay set been found dense enough to resist their boring action. Some varieties of Teredo can even cut their way through poorly mixed concrete.

WHETHER the sawdust Teredo consumes as untilized as food is a matter of dispute. Most authorities think that it is, but Clapp does not agree. He maintains that Teredo's boring is simply an adventure in home building, and that he subsists on plankton, the microscopic drifting life of the seas. Temperature of water determines the span of each year's Teredo activity. in Boston it is two months; in the tropics the Teredo works the year round. An untreated tumber which would less 30 years in Lab.

rador may last only one year in Panama. Why will these boerrs suddenly invade a harbor which has been unmelseted for decades? The answer usually lies in changed conditions. A three year drought explained the infeatation at San Francisco. With very little fresh water going into the Bay, sainity rose and the boerrs went to work to do staggering damage. Particular attention is now being centered by Clapp on New York

Those that land on mud and rock quickly perish. Those that alight on timber are more fortunate. After two hours of furious work their minute heads, shaped like clam shells, have rasped away a shelter deep enough to enclose the entire body.

As it progresses from the embryonic to the adult stage, the Teredo becomes a rather complex and impressive creature. It sheds the fragile shell with which it does its boring and grows another which is more sturdy.

The Terede maintains contact with the outside world, which is to say the sea, by two hair-like branches of a forked tail. Through one it sucks in sea water and food in the form of minute sea life and through the other exhausts its body wastes. The opening through which these two siphone extend is no larger than a pinhead, but this portal— a unperbly constructed valve—will serve Toredo even though its body attains a leanth of six feet.

Teredo is a master architect, and a superb housekeeper. It removes all debris by the only means at its disposal: by eating it. It lines its tunnel neatly with lime. In some cases this tunnel is so

Honeycombing of a pile by marine borers in only two years, despite the cold waters of Newfoundland

Harbor. In the past, pollution of this port has been so great that borers could not survive. When the present clean-up program is completed, they will almost surely arrive in large numbers and go to work. Such a thing happened elsewhere, notably at Lynn, Massachusetts.

Keeping track of borer activity in a hundred harbors scattered throughout the western hemisphere is the monumental task the Clapp Laboratory has set for itself. Are borers on the increase in Puerto Rico? And what varieties are at work in New Brunswick? Are they harmless ones which work in water too deep to damage piling, or the destructive Limnoria? To answer such questions Clapp's endlessly active mind has devised many ingenious aids. One of them is a test block which gives a continuous record of borer activity; another is a trap which captures specimens for identification.

THE test block is engaging in its aimplicity. It consists of nine small blocks of pine—ideal Teredo fodder bolted to a strap of iron. Each month a block is removed, and a new one is bolted in its place. Biologists examine the block in the laboratory and compare it with those removed from the same spot at earlier dates. They can thus determine whether borer population is rising or failing.

The Teredo traps consist of 30 shingles bolted together. Since the borers refuse to cross a crack, they confine activity to a single shingle. When the bundle is unbolted, whole specimens may be removed, examined, and identified.

Test boards are kept at over 400 stations, and traps at scores of others. Maintenance of a board costs about 25 a month and a few companies pay for this service, but the great burden of expense falls on the laboratory. Test boards occasionally reveal a tremendous upsurge of borer population. In severe cases, as many as 100 Teredos have been found boring within a single cubic inch of wood. Such cases demand instant attention. Several times Clapp has found it expedient to telegraph dock owners quickly to remove all valuable goods from their property because their docks were in danger of collanse.

Once test boards indicate that bores are at work on the piling which supports a large dock, a diver gove down to make an examination. Some of the divers who work for Clapp are so learned that they even know the Latin names of the commonest borers With astonishing accuracy they can estimate the amount of damage and from this the attructural strength of supporting material left under the dock can be calculated.

Corrective measures are determined by local conditions. Where damage is severe, piling must be replaced. Some times concrete corsets are poured around partially damaged piling. Sometimes

The exterior of a badly bored pile gives an appearance of solidity

they are covered with metal sheathing. Damage to the vast, \$25,00,000 Army Base in Boston was so severe that Clapp recommended that bulkheads be built which would completely enclose the substructure of the dock, and that fill be then pumped in. This fill prevented further activity of the borres, some ready access to salt water is necessary for their existence.

If timbers in new construction are pressure-tracted with good quality crossote they get complete protection But in some cases the quality of crossote is so low and method of application so had that even this treatment is valueless. The Clapp Laboratory tests the protective power of these materials. Through ignorance or false conomy, hundreds of thousands of untreated piles are still being used in United States harbors. As a result, docks last only a third as long as

they should and must be replaced often.
Still, one good word can be said for
marine borers: without them the world
would have no open harbors. Long ago
harbors would have been clogged with
rotting driftwood if the borers didn't

destroy this debris.

The laboratory which is fighting the marne termites practically single-hand of sends no bills. If clients—which include oil, railroad, and steamship companies—are satisfied with work done for them, they assess the value of service rendered and send checks accordingly As a possible commentary on human nature, note in passing that the laboratory always totters uncomfortably on the verge of bankruptcy. Yet William F Clapp will have things no other way.

"FRIENDS are always attempting to F make me change my ways," says this genial biologist. "They want me to keep books and send bills and do things like that. But I'm damned if I will. I am a biologist, not a bookkeeper."

If a check arrives and Clapp feels that he has not carned the sum sent, he returns it. Officials of a large sugar company called for advice about a new dock A telephone call saved them thousands of dollars and they sent a \$500 check in appreciation. Clapp returned it Not we have the five minute telephone call, he contended, could be worth that much. Another time he refused an annual retainer of \$15,000 or from a company which made a wood preservative.

preservative. The pleasant, blue-eyed biologist has done practically everything to the Teredocept extent. He hopes to get around to this some day. Meanwhile he goes along adding up new facts whose application will save millions of dollars. The aboratory had a sazeable deficit last year. It took in \$11,000 and spent \$13.5.

00. But Clapp is not deeply concerned. "If your work is good enough," he feels, "neople cannot affor to let you fail."

OUR POINT OF VIEW

Battle is Joined

H OW long World War II may last is anybody's guess. How difficult it is going to be for the United States is a different matter. Though not involved, we shall, nevertheless, be faced with a problem of defense against forces that are insidiously subtle. It is not our war, yet our fight to stay out of it will call into high the stay out of it will call into mon sense, all the skill of our government.

As this is being written, the war in Europe is but a few days old. Radio and the newspapers have, however, given us already a vast amount of propaganda and counter-propaganda. One side of this war behind the war will have little effect on the individual for he will have formed his opinion prior to the outbreak of hostilities, but the propaganda from one's chosen side will tend to strengthen his belief in the righteousness of one cause. Inflammatory rumors will have their influence. Logic may be forgotten and emotion will rule. Hatred may become a neurosis, and the multitude may then clamor for blood, may insist that we enter the fight with men and guns. This we must guard against with all the might of whatever logic and sane thinking are left to us.

The United States is today in a fortunate position in respect to world politics and power. Our foreign commitments relate wholly to the American hemisphere. We have a battle fleet second only to that of Britain, and a large program of ships building and planned. A plan has been launched to train thousands of air pilots each year, and the personnel of our Army and Navy have been increased and rendered more efficient. More planes have been ordered to be delivered over a period of years to our military forces. Mechanization of the Army is proceeding with the efficiency that comes of deliberate care. Construction of sceres, perhaps hundreds, of new American-type tanks—the best in the world-goes on apace. Slowly all infantrymen are being equipped with the world's finest rifle, the Garand semiautomatic.

The so-called "Stock Pile" Act, passed by Congress lest spring, is enabling us to store up necessary vital products them may be ut a spoint lower than is at present possible. A War Resources Doard has been formed of scientific and industrial leaders. Industry has long aince been so organized that, if war should be forced upon us, each plant could guidely and efficiently go on a

war-time foogling. "Educational orders" have been given to many of them. Other things, important to us in war, have been mentioned recently in these pages. For example, there is the new process of molding airplane fuselages, which would increase our plane production enormously. Another is the sizeable supply of management from Cuba.

This magazine has long been a pro ponent of the philosophy of "preparedness for peace" and believes that the above review, sketchy though it be, indicates that particular and important kind of preparedness. Our might is vastly greater than in 1917, our organization so superior that there is no comparison Hence, it is our belief that no nation will wittingly antagonize us, insolently dare us to go in on the opposing side. It is ourselves that we must watch lest we become dupes of silver-tongued agents who would embroil us in troubles out of our own bailiwick. We may give our sympathy-which is of the heart-where we will; but through it all we must keep our heads.-F. D. M

Communication

AT first thought it would seem that the peculiar techniques of radio broadcasting—spot news. high-geared commentators, and so on—would give the whole world a grandstand seat in the event of war. But when the situation grew tense in central Europe, when fateful September 3 rolled around, the humming of the air waves brought thinking people to the realization that a communicating system was more than alling down on a job; it was providing a medium whereby misinformation and no sieve was offered through which they could be separated.

The preceding editorial hints at the propagands possibilities of radio. But there is much more to the story. Operation by belligenents of stations under faked call letters, spurious dispatches. "shanketing" of legitimate stations—all teach us that we will do well to take radio news broadcast, at least for the duration, with more than the proverbial grain of salt.—A. P. P.

Howling For Knowledge

A DOZEN years or so ago it was ascertained by means of polls conducted in the interests of the press that the branch of science which "pulled" hardest with the general newspaper-reading public was the one having the least practical usefulness—astronomy.

This startling discovery astonished the newspaper world. Since the press is tupod, it gives the public just what is asked for and it therefore greatly increased its regular ration of features and news items on astronomy. This astronomical emphasis has been going on in the press for a decade or so and now it is bearing a heavy crop of fine fruit. The masses, and no longer merely a limited number of better-than-average educated enthussasts, have now become strongly astronomy conscious.

In Chattanoga a small group of advanced ansteur attronomers recently anneed ansteur attronomers recently pooled their efforts to make possible a public observatory, whereupon thousands and thousands of people—just average "folks"—vastied and continue to vasit that observatory. Mountaineers have tramped in from the distant bills to see the stars through a large telescope for the first time in their lives

Not long ago David Dietz of Cleveland, science editor of the United Press, a man who has one foot in astronomy, the other in the newspaper world, decided to make a test of interest in astronomy among the masses and put on a public star party Ten telescopes made by amateur astronomers in Cleveland were rounded up, placed in a public park, and directed at different celestial sights; one at Mars, another at Jupiter, and so on. Previously the event was announced in local papers. Would the party be a failure? Would the people take one look and amble off home? Would they come at all?

More than 5000 people stood in line till after midnight awaiting their turn to see what these objects, about which they had been reading in their papers for years past, look like. Patiently? No. Cleveland had to send two squads of police to keep them in line. Pop venders appeared out of nowhere and did a rushing business. When, at 1:30, the last cager star-gazer left the park, it resembled a battle-field, littered with paper, Crackerjack boxes, bottles.

Only a howling mob? Yes, but not a disorderly one—just eager. Only tabloid readers? Probably largely so. Is that bad? No—all to the good!

These successes give answer to those persons, schooled but essentially ignorant, who still insist on rating swerpthing on a basis of its practical usefulness. It's a mighty good sign when 5000 of the plain people will stand in line and veil "flurry up" in order to get a better didea of man's place in the universe; for that is suspected of being the real philosophy behind it all—4.6. C

Hunting The Mesotron

W HEN confronted with the evermounting clutter of assorted
to the confronted physicists in recent
years, one naturall instruction to the astonhard with a state of the confronted physicists in recent
years, one naturall instruction to the astonhard when all motorities are proposed to the confronted physicists of the confronted physicists of the confronted physicists of the physicists of the physicists of the physicists of the physicists mestly in the physicists of the mesotron.

Although there has been considerable controversy as to where it is found in nature, it is now known that the meso-tron occurs only in the cosmic rays. These rays, which raim in upon us constantly from outer space, have been known for many years. Nevertheless, the question as to just what they were was not settled until scientists turned to the Wilson chamber with which they proposed to study their true nature.

The Wilson chamber consists of a shallow glass cylinder covered with a glass plate. The interior contains a small amount of liquid, such as water or alcohol, which evaporates, filling the chamber with vapor. In the bottom is a piston which, when suddenly pulled out by a suitable mechanism, causes the vapor to expand and condense. If the expansion is very carefully adjusted so that condensation just fails to occur, any electrons or other charged particles which traverse the chamber will leave faint tracks of condensed vapor in their wake. By photographing these tracks, much can be found out about the nature of such particles. For example, their velocities can be found if the chamber be put between the poles of a large electromagnet. The effect of a magnetic field upon a moving charged particle is to cause it to be deflected in a direction perpendicular to the magnetic field and to its original path. Thus the track will be bent by the magnet into a circle. The radius of the circle is proportional to the momentum of the particle and, since momentum is the product of mass times velocity, knowing the mass, the velocity can be found.

At first, experimenters merely set up their chambers and expanded them at regular intervals, hoping to catch cosmicray tracks by accident Considerable improvement was made in getting photographs when Geiger counters were used These instruments consist of a thin metal cylinder surrounding a wire and put in side an evacuated tube. High voltage is This Recent Addition to the Fast-Growing Family of Sub-Atomic Particles has Already Created a Place for Itself in Physical Theory and Experiment

By CHARLES W. SHEPPARD

connected between the wire and the cyl inder and adjusted until just helow the point at which a discharge will occur If a cosme-ray partiele shoots through the tube, the discharge is set off and can be made to trip an electrical circuit, expanding the chamber With such an arrangement, it is possible to catch a cosmic-ray track at every expansion

Figure 1: Two cosmic-ray showers, one is the chamber wall and one in the plate, show that particles from showers produce showers. Each particle has an energy of several billion volts. (See the text below.)

In practice, two counters are used, placed one on each side of the chamber and connected in such a way that the chamber expands when the particle goes through both. Thus, the chamber operation of the chamber of the c

The study of cosme rays with the Wilson chamber was numediately fruitful. When a barrier of lead was put into the chamber, many pictures showed a strange phenomenon. A cosmuc-ray particle entered the chamber from ahove and went on into the lead plate. It energed from the other side and with it, like an explosion, came a regular forcest of other particles (Figure 1),

Such occurrences are called showers. Up to this point, the result had been quite straightforward. There was good reason to believe that the tracks which were observed were caused simply by electrons. In particular, a study of the shower particles showed that those produced by showers could themselves produce showers, and their energy loss in going through the lead plates showed that all were electrons. However, the many workers on the cosmic-ray problem frequently observed other particles, and although their tracks looked just like electron tracks, they behaved in a different manner (Figure 2). To understand why the scientists were puzzled by these other particles, we must consider how charged particles lose their energy m traversing matter.

LET us consider first a fairly heavy particle such as the nucleus of a hydrogen atom, called the proton. Since the distance between the atoms in a plate of lead is about 100,000 times the size of the proton, the latter cannot lose energy by friction in passage through it, as would a bullet in a piece of wood. It is known that almost all the energy loss which a proton suffers is due to the electrical forces that it exerts on the electrons in the material through which it passes. About thirty volts of energy are needed to pull an electron from an air molecule. The number of these dissociated air molecules, or ions, can be measured and it is found that, in air, a broton of 1,000,000 volts energy creates so many of these ions that it loses almost all its energy in less than half an inch of air. In the case of lead, it will scarcely penetrate at all. Energy loss by ioniza-tion, as this type is called, is characteristic of heavy particles which do not move with very high speeds. Although the process is very complicated, it has been found that the energy loss is greater the slower the particle travels, and a measurement of the rate of energy loss gives an approximate idea of the velocity of the particle.

A totally different type of energy loss is also known. Particles such as electrons, which are light but travel at high speeds, lose their energy by giving out electromagnetic waves when they pass through matter. This is how the rays are produced when the electrons in an X-ray tube strike the target. This type of process is called energy loss by radiation.

From what has just been said one can see that a study of the way in which a charged particle loses energy should give quite a bit of information about it. Such energy-loss measurements were attempted but were hard to make. The energies of cosmic-ray particles run in billions of volts. Such particles move so fast that none but the largest magnets will bend their paths enough to permit measurement. However, careful work gradually yielded the necessary information. As the measurements slowly accumulated, suspicion grew into certainty. Those tracks which produced, or were produced by, showers lost energy in just the way that electrons may be expected to do and were undoubtedly electrons On the other hand, those tracks which occurred without showers were different. for they had a penetrating power very much greater than any other charged particles heretofore known. Of the many experiments to demonstrate this penetrating power, one of the most spectacular, in which the particles were made to pass through more than seventeen inches of lead, was made by Street, Woodward,

and Stevenson, at Harvard University. In 1937, Dr. Carl Anderson and Dr. Seth Neddermeyer, of the California Institute of Technology, put forward a tentative explanation in a paper published in The Physical Review. This paper contained a plot of the energy

Figure 2: "Picture" of a mesotron. The particle comes in with high speed, making a very faint track, alows down in the central plate, and emerges going more slowly, so is shown by the heavier track as well as by the shormer convenirs.

losses of cosmic-ray particles, showing how the non-shower particles lost much less energy than the shower particles (Figure 3). Let us suppose, they said, that the unknown particles are heavier than electrons but lighter than protons. Then particles of a given momentum will travel faster than protons and not lose much energy by ionization. On the thorth and, they would not travel so fast as electrons and would not lose much energy by redition. This would explain their low energy loss or great penetrating nower.

In order to substantiate their theory, it was thus necessary to determine the mass of these particles. The difficulty lay in the fact that only the momentum can be measured when particles are deflected by a magnet. The mass is known only when the velocity can also be found. Several workers at once attempted to measure the velocities of the unknown particles by the following method:

A charged particle traversing a cloud chamber leaves a track because of the ions it produces in its path. The vapor in the chamber prefers to condense on these ione and with the right expansion every ion picks up a tiny droplet of condensed vapor. If the expansion can be delayed a fraction of a second after the particle passes through, the ions will have time to drift apart so that the droplets can be counted with a microscope. If the number of ions in each centimeter of track is counted, the rate of energy loss can be determined and this will give an approximate knowledge of the velocity of the particle. Such measurements are actually a good deal more difficult to make than a description would indicate. Conditions must be just right and not every picture will do. However, in 1937. Street and Stevenson, and, shortly afterward, Anderson and Neddermeyer, obtained the pictures they were looking for and forged the last link in a chain of evidence extending back over several years. Measurements of the mass of the particles from these pictures showed that they were somewhere between one and five hundred times as heavy as ordinary electrons. Several suggestions were made for naming the new particle and Dr. Anderson's suggestion of mesotron received the most support.

CCIENTISTS had scarcely had time to in inquire as to what place there was for the mesotron in existing theories when a holt from the blue came in the form of an already existing paper in the rather maccessible Proceedings of the Physico-Mathematical Society of Japan. In this paper, published almost two years before the discovery of the mesotron, the Japanese physicist, Yukawa, had announced a theory explaining the force of attraction between the neutron and proton. The theory

stated that these unknown forces holding the atom together could be explained if one assumed that there existed a new particle with the charge of an electron but of larger mass. If, as many scientists believe, the Yukawa particle actually is the mesotron, then not only is an experi-

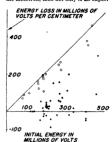

Figure 3. Principal clue to the existence of the mesotron. Diagonal line represents the total loss of energy in one centimeter of platinum plate. The circles clustering close to this line are electrons. Dots clustering near the bottom of the graph are mesotrons

mental discrepancy accounted for but also a vacancy in theory is filled by its discovery.

Needless to say, the appearance of the meetorun upon the scene has stimulated the whole field of cosmic-ray research to new activity. Experimenters are redoubling their attempts to make accurate measurements of cosmic-ray tracks using larger magnets and Wilson chambers than those formerly employed. Thus more precise information will soon be obtained with such apparatus.

Let us now return to the question we made at the beginning. Is particle hunting a sort of glorified insect collecting or does the physicist find the particle one day at lunch in his soun? In the first place, both alternatives place an undue importance on the particle itself. Such a discovery is never merely a new head to hang on the wall of the physical laboratory. Instead, it invariably represents an important contribution to physical theories and thus frequently extends human knowledge in many different directions at once. Let us consider the senior member of the "tron" family, the electron. This particle is a crucial link in almost all the physical theory developed since 1875. It is safe to say that, without our knowledge of the electron, we would have no X rays, no radio, and no long-distance telephone. Perhaps one day, the mesotron will be as indispensable.

COULD WE DEFEND OUR PORTS?

WHETHER or not important American ports are sufficiently well fortified to stand off a possible invasion remains an open question. Only an actual attack upon noe of those ports would provide the answer. The drawing on the opposite page is presented as an example of what might happen but, unfortunately, military strategy is not so simple as that. With this drawing before us, we still must lean heavily upon past military lessons and experience.

Bombang planes cannot cross the wide occans that surround us and still deal any effective blows against us. Hence, any invader would have to depend upon only those planes which his carriers could bring. This immediately unlifies any belief which he might have that the airplane has changed naval warfare conditions radically since 1915. In that year, the British fissec at the Dardanelles proved rather conclusively that it is futile to launch a naval attack upon land fortifications.

We are here concerned not with why an enemy might attack us nor how he would get through our first line of de-fense—the Navy—but rather with the possible reception he would get were he suddenly to appear on our "doorstep." For this purpose, we have shown mything all smith City, the details of which are bunched and hence thrown out of perspective for obvous reasons.

As soon as the enemy's fleet nears the city-which might not have much warning-preparations for the defense of the port will get under way according to plans long before worked out. Necessarily, these plans include bringing up more guns and equipment, plane detectors, range finders, searchlights, and many additional men from camps near the city. Firing of anti-aircraft guns would begin long before the fleet itself is in sight. Its planes, based on carriers left perhaps 75 miles out at sea, will attempt to destroy gun emplacements in the city's forts. Doubtless, they would resort to the practice of divebombing, an American trick learned by foreign aviation, oddly enough, from an American moving picture, "Hell Divers," several years ago.

This surprise attack from the air military and the cognization of the defense would, nevertheless, proceed rapidly and efficiently. All available units of all our armed forces—Army, Navy, and Air Corps—would be co-ordinated and unified under an appropriate commander.

An Imaginary Attack on a Mythical Port Shows Sort of Action That Would Take Place

He would keep track of, and direct the movements of, the additional forces coming up from the rear, most of which is motorized and some, as in the case of the 12-inch and the 16-inch guns, or ailway mounts. These latter large guns would be run in on the railroad apur shown at the right of our drawing. The 16-inch guns on railway mounts, as well as those of the forts, would be able to match anything the enemy capital ships would have, being able to throw one-ton shells for a distance of about 40,000 yards.

Against the enemy's airplanes would be directed the fire from several types of guns. Most important would be the 3-inch guns which fire about 25 highexplosive shells per minute to a height of 24,000 to 28,000 feet. Until 1938. we had only a few of these rather small guns. In that year we added about 340 of them to our armament, and since have added more. Another anti-aircraft gun which the defending forts would use is the 37-millimeter gun. This mobile arm fires explosive shells weighing approximately a pound and, being loaded with clups of five and ten shells. has almost machine-gun speed of fire. Furthermore, low flying planes would meet deadly streams of metal from 30-caliber and 50-caliber machine guns. The Spanish civil war apparently proved that machine guns, as contrasted to those firing explosive shells, are ineffective against modern, metal-clad planes. In spite of this fact, it is believed that these efficient machine-guns, properly controlled and operating in groups, could cause serious damage to planes.

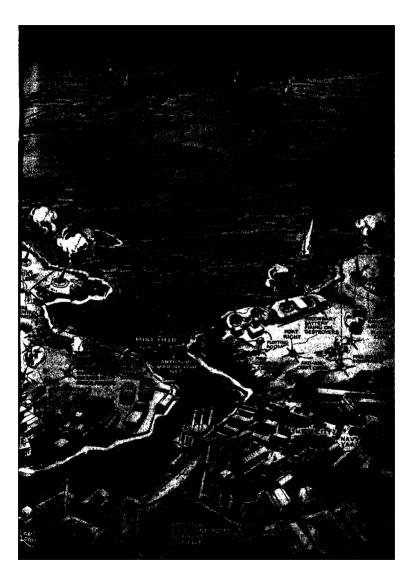

ONCE an enemy plane is detected by the defense, an ingenious range finder, shown in the drawing near the anti-aircraft batteries, would go into action. This finder is practically automatic. As an observer moves it to keep its widely spaced cross-hairs aquarely on the enemy plane, that movement actuates gun-pointing equipment to make the guns follow the plane's movements closely.

As for the fleet itself, wariness would characterize its actions because of the lessons of the Dardanelles. The enemy capital ships would form a line of battle just beyond the range of the largest guns of the forts. The advantage lies with the land guns because of their permanent emplacements which give greater stability and because their firecontrol stations can more accurately plot a moving ship's position. These fire-control stations - shown on the drawing in both Fort Left and Fort Right-form the bases of triangles while their converging lines of sight make the apex of that triangle. The exact position of the ship at the apex is therefore easily calculated, in the plotting room of Fort Right, by the mathematical process of triangulation. Planes spotting shell bursts among the enemy ships. and also "tracking" those ships to predict their movements, would provide further data.

Since the enemy's principal purpose would be to get his capital ships close enough to deliver his 14-inch or 16-inch shells in the forts, he might try to sneak in under cover of a smoke screen. This screen would be laid by squadrons of destroyers which would dash in closely in a sweeping curve, firing their smaller guns furiously. The high speed of these destroyers increases the possibility of their escape but, even if some of them are destroyed by gun fire, their loss is not to be compared with that of a capital ship. It is during their dash close inshore that the secondary guns of the defenders, hitherto useless because of their shorter maximum range, must go into feverish action.

Our drawing has its necessary limitations. We have shown, for example, only one small submarine boat net and a mine field that is actually too limited for practical purposes. These things are more symbolic than actual, for we wished to show only the essentials. In real warfure, far more ships and guns, mines and nets, planes and anti-aircraft guns and detectors would be in such an action. Also there are many other factors, too confidential or too speculative to be mentioned here, that would have a bear ing on the fight. In any case, it is believed that an attack of this sort would result in a stalemate. This does not mean that our ports are invulnerable. They aren't. It is only our ability to draw upon an immense hinterland for enormous support which could save us in such a situation. We do need more large-caliber guns, more and larger antiaircraft guns, and many other important things, but that is another story.

Eclipsing Binaries

It may be questioned whether there is really a "royal road" to the solution of any problem of nature; but some routes do lead us, with less difficulty, deeper into the regions which we desire to explore.

One of the most important of these routes, in our search to understand the stars, is found in the study of the pairs which eclipse one another. It has long possible to the stars are stars, is found in the study of the pairs to been realized that from good observations of these systems we can find out things not directly accessible in any other way, such as the real sizes of the stars, their densaties, and the actual brightness of their surfaces.

But even the finer details of the lightcurves, which might almost be called the "embroidery upon the main pattern," are singularly informative.

For example, when the brightness of an eclipsing star (that is, the combined light of the pair, which could not be seen double in a telescope 50 timere more powerful than any ever constructed) has been accurately measured and the light plotted against the time, it is found that, between the deep dips arising from the successive eclipses of each star by the other, there is a smaller, each star by the other, there is a smaller, the eclipses, the light is brighter than where the eclipses are just over or just ready to begin.

The explanation of this behavior (which was first noticed in the bright star Beta Lyrae) has been known for almost 50 years. When the component stars are close together, each will be distorted by the tidal forces arising from the attraction of the other. This will make them egg-shaped, with the long ends pointing at one another. As they revolve in their orbits, about their common center of gravity, they will rotate at the same rate, and continue to point toward one another. Half-way between eclipses, where the line joining the stars is at right angles to us, we will see them broadside on. At the middle of eclipse (if the orbit is edgewise toward us) we will see them end on (one behind the other), and just outside eclipse they will be nearly end-on. Half-way between eclipses, therefore, the star-disks will have a greater apparent area than just outside them, and, naturally, we will get more light.

This ellipticity effect has been found in dozens of stars—indeed, in almost all cases when the observations of light are accurate. We might expect to find it bigger when the stars are very close together—and the celipses consequently

A Striking Example of the Extent to Which the Astronomer, Armed with but a Few Observational Data, Can Sometimes Go in Unraveling Puzzles

By HENRY NORRIS RUSSELL, Ph.D.

Chairman of the Department of Astronomy and Director of the Observatory at Princeton University Research Associate of the Mount Wilson Observatory of the Commette Institution of Washinston

occupy a considerable part of the whole period—than when the eclipses are short and the stars far apart; and this actually happens

The shapes which stars, tidally distorted by their mutual attraction, would assume can be calculated. The theory is fairly simple, in the first approximation (though it becomes intricate when the bodies are very close together). It is found that the shapes depend not only upon the masses, radu, and mutual distance of the stars, but also upon their internal constitution. If the material (supposed to be fluid, so that it yields freely to the tidal forces) is all of the same density, the clongation will be large; but if it is much denser near the center than at the surface the distortion is much smaller. In the extreme case where practically all the mass is concentrated at the center, it is only 40 percent as great as for a homogeneous body.

HERE then appears to be a royal road leading us to knowledge about the inaccessible interior of the stars. As long ago as 1912, Shapley applied this method, finding that the ellipticity of such stars, derived from observation, agreed quite closely with the values calculated by Sir George Darwin for homogeneous massess of fluid.

There was, however, one difficulty The calculations just described had been made upon the assumption that the been made upon the assumption that the disk of each star (seen sufficiently magnified) would appear uniformly bright all over. Now the only star we can actually observe in this way is the Sun, and it does not look like this, but is only about half as bright at the edge as at the center. The reason is that the light which reaches us from points near the apparent edge escapes obliquely, and on the average comes from cooler layers nearer the surface.

We might expect some "limb-darkening" of this sort in the stars also. It is not hard to calculate its effects in the case of an ellipsoidal star. If there were two stars of the same size, shape, and average brightness, one presenting a uniformly bright disk and the other darkened so as to be very faint at the limb, it is found that the difference of brightness between the end-on and broadside-on presentations would be 60 percent greater for the "darkened" case than for the "uniform." An observed variation can therefore be produced by a "uniform" star of a certain difference in long and short diameters; by a "completely darkened" one for which this difference is only five eighths as great. and by a whole set of bodies of intermediate shape and intermediate degrees of darkening toward the limb. Unless we can find the degree of darkening in some other way-which is still very difficult-we are left in considerable uncertainty about the real shapes of our stars. and the actual internal distribution of density.

But now another royal road seemed to open up. If the stars are elongated as described, their mutual attraction will not be quite the same as if they were spherical. The effects of this have been known for more than two centuries. No perceptible change will be produced on an exactly circular orbit; but, if the orbit is eccentric, the line of apsides (passing through the points nearest the center and farthest from it) will slowly advance, in the direction of the orbital motion. The rate of this advance depends on the radii, masses, and ellipticaties of the stars, and also on their internal constitutions, being a maximum if they are homogeneous, and falling to zero when all the mass is concentrated in tiny particles at their centers. This impossible, but theoretically limiting. case is known as the Roche model (from the name of its inventor).

If an eolipsing pair has a circular orbit, the alternate celipses of each star by the other will come at equal intervals, and last equally long. But if the orbit is cocentric, both the intervals and the durations will usually be unequal. If the line of a paicles is moving, the intervals between the eclipsee will above the change, when go have a company to the company of the comp

tween two limiting values, and repeating these changes after a whole revolution of this line.

For most of the stars which have been observed, the orbit appears to be circueobserved, the orbit appears to be circuelar. But in a dozen or more cases uncessive minima prove that the orbit is eccentrician, and, in almost all these cases, the intervals are changing, showing that the line of spides is moving. In two systems a complete revolution of the apsides has been observed.

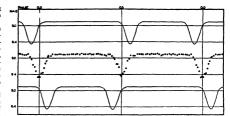

Knowing the rate of this motion, and the sizes and relative masses of the stars, we can calculate the degree of concentration of density toward the center. For the star Y Cygni—the first to he reliably observed—Dugan and the writer found, several years ago, that the concentration must be great

But again the once-royal road appeared to be blocked. The theoretical calculation of the attraction of the stars on one another had been made for hodies of the shapes which they would have at their average distance apart; but no allowance had been made for changes in this shape

NOT long afterward Walter went deeper into the mathematical problem, assuming that the two ellipsoidal stars were rigidly fixed in size and shape, but free to turn on their axes unevenly, and point a little away from each other at times. His analysis led to the remarkable conclusion that, in this case, the line of apsides moved backward while two atars undergo whattons such that their long ends oscillate to and for about the line joining their centers (usually they oscillate with different periods).

Given his assumptions, his conclusions are mathematically sound; but, about a year ago, Cowling pointed out that real stars, being gaseous, would not behave at all like the "frozen," rigid bodies of Walter's theory. As the distorting forces changed, while the stars moved around their orbits, the mobile gaseous masses would tend to take new shapes, corresponding to the new forces; and this adjustment would be so quickly made that it is practically safe to disregard any lag in it, and assume that the shapes of the stars are determined by the forces at the moment, and are most elongated when the two are closest together. Working out the details-no simple task-he found that the apsides move forward, but at a little more than twice the rate originally calculated by the writer.

The theoretical problem has now, apparently, been cleared up. When the new equations are applied to the actual data—as has been done in detail for the best-observed stars by Sterne, and approximately, for a larger number, by the writer—it is found that, in every

Light curves of an eclipsing binary with eccentric orbit and rotating line of apsides. Phase in the orbit is measured toward the right. The distance between papels are placed in the orbit of the measured toward the right. The distance has represent the apparent magnitude of the pair of stars, a measure of their brightness. The dips in the curves are due to the eclipse of one star by the other. The center curve represents the average of all observations. In the upper curve the stars are at periastron (closest together) in the latter half of the period, mildway between the two minima which occur closer together. The lower curve represents the situation 12 years later, when the elliptical orbit has swang halfway around, making periastron occur in the earlier half of the period. This variation of the time interval between eclipses is due to the greater speed of orbital motion when the stars are closest together.

However, the above diagram is not immediately related to the particular stars discussed and mentioned in the accompanying article. Rather, it is shown as "a very pretty illustration," as Professor Russell wrote in suggesting that it be reproduced, "of the changes due to locating applieds in an orbit," and it is taken from an article entitled "The Apsidal Rotation of GI. Carinas," by Henristte Swope and Hardward Salpely, in the Bulletin of the Harvard Callege Observatory for July 1, 1938 (No. 999). In the absence of Professor Russell in Europe the above explanation of the diagram was prepared by Prof. D. B. McLaughlin of the University of Michigan. Regular readers of Professor Russell's articles may be interested to know how the illustrations are selected. Sometimes be prepares rough sketches which are redrawn by this magazine's draftman. More often the illustrations are selected by the editors, whose responsibility they therefore are

case, the central condensation is high The motion of the apudes is never as great as 6 percent and usually less than 2 percent, of the value which it would have if the stars were homogeneous. It follows, approximately, that the central density of the stars is always at least 20 times as great as the mean density of the whole star, usually more than 50 times as great, and occasionally as much as 300 times.

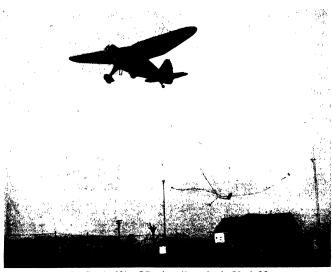

So far as observations of this type go, the results are consistent—though a lot more observations will be needed to get more accurate data. But an alarmid discrepancy now appears between the results of the one method and the other. The two royal reads end in different places—one indicating that the stars are not very far from being of uniform density, and the other that the increase of density at the center is very great.

The answer to this puzzle comes from some theoretical work of Chandrasak-har, who found, six years ago, that a distorred star of this sort should be faintest at the ends, remote from the center—the surface-brightness being proportional to the intensity of gravity as this would be observed by an imaginary inhabitant of the surface-brightness as this would be observed by an imaginary inhabitant of the surface.

For such a body the difference in brightness between the end-on and onbroadside views is much increased—infact, very nearly doubled. This was first pointed out, five years ago, by the late to (in English) in a Japanese scientific to periodical, and escaped notice till the matter had been treated by various other investigators.

When allowance is made for this and for the effects of "darkening" (which operate almost independently) the discrepancy disappears. The fairly large changes in light which are observed between eclipses arise largely from the difference in brightness between the ends and the middle of the elongated stars—and are increased by the limbdarkening. The real shapes of the stars are not far from those of the Roche model—just as the changes in the orbits indicate.

Much more work remains to be done before this mine of information about the surfaces and the interiors of the stars becomes exhausted. Meanwhile, it is interesting to note that our present fairly satisfactory knowledge has been reached by the work of investigators coming from this country, England, Germany, India, and Japan.

Specially equipped Stinson Reliant plane picking up a bag of mail "on the fly"

AIRMAIL FOR SMALL TOWNS

IRECT airmail service to small cities and towns, previously reserved for large centers of population where the volume of business warrants large airports and mail-handling facilities, is now daily available to 58 localities throughout Pennsylvania. West Virginia, Ohio, and Delaware. Through development work by All American Aviation, of which organization Richard C. du Pont is president, an airmail delivery and pick-up system invented by Dr. Lytle S. Adams has been reduced to practical operation. Flying the air-ways in specially designed and equipped ships, "sky mail clerks" are now able to make deliveries and to pick up mail without the necessity of landing. At the time of writing, the system is in operation with six experienced pilots, some of them of national reputation, and four "sky mail clerks" constituting the flying personnel.

The success of the system, and the

Pick-Up and Delivery Without Landing . . . Made Possible by New System . . . Can Bring Fast Mail Service to the Most Remote Areas

By DR. ALEXANDER KLEMIN
In Charge, Danish Guggenheim Behool
of Aeronautics, New York University

regularity with which the service is carried out, indicate its entire feasibility. There is no doubt that it can readily be extended to other sections where its advantages are desired.

While full technical details of the exact operations of this new system have not as yet been released, the accompanying photographs and following description serve to give the fundamentals. The ground equipment necessary consists merely of two steel poles, 30 feet high, set in concrete foundations 60 feet apart.

Each pole is topped by a brilliant orange marker. Stretched between the poles, and attached by spring clips, is a trans Ter rope from which is suspended the mail bag to be picked up.

mail nag to be picked up.

In the planes used for this service, all standard interior equipment has been removed except the pilot's seat, thus making room for mail bins, pick-up gear, and a seat for the clerk who also is responsible for the operation of the mail-handling apparatus. With this relatively simple setup it is possible to deliver and

pick up mail while flying at a speed of between 90 and 110 miles an hour. Since speed is the essence of sirmail service, it is interesting to note here that, flying 1540 miles daily and making 75 pick-ups to serve the 58 community of the state of the serve the 158 community planes are carrying on a regular schedule at a werge speed of 100 miles an hour even under adverse weather conditions. Since the stations are from five to 22 miles apart, such service could not possibly be mantained if it were necessary for the plane to land at and take off from every station.

Deliveries and puck-ups are made in one trip through each station, the operation being as follows: The clerk lowers by hand the bag for delivery, which is linked to the plane by a rope ending in a release mechanism that is under the control of the plot. He then lowerthe grapple hook on one end of a cablethat is wound on a shock-absorbing winch in the plane. The pick-up cable extends from the bottom of the fuselage about two feet forward of the delivery open and the two lines are prevented

from fouling by their drag/weight ratios which give them different curves in

When the delivery bag is released by the pilot, before the plane reaches the two poles and transfer rope at the station, it falls clear of the pick-up cable. The plane then passes between the poles at an altitude of 50 to 70 feet above the ground. The pick-up pable then crosses the transfer rope and slides across it until the prongs of the grapple engage the rope and pull it free from the poles. As the grapple pulls on the transfer rope, the mail bag slides along the rope away from the grapple, a simple restricting

fitting slowing up the travel of the bag as it approaches the end of the rope where at is checked. It is really this alide fitting, which absorbs much of the shock of contact, that makes possible this type of pick-up without impossing undue strain on the cable. The remander of the shock is taken up by the absorbing mechanism in the plane. It is stated that

Above: The steel grapple with which sirmail pick-ups are made. Left: A "sky mail clerk" operating the winch by means of which the bag of mail is reeled into the plane. Extreme left: Close-up of combined winch and shock-absorbing apparatus which is mounted in the plane. The sir-oil shock absorber operates when the grapple hooks into the line and prevents undue strain being imparted to the plane itself. Below: The fiber and rubber mail bag, showing the restricting fitting which slides along the rope and helps absorb transfer energy

the pick-up is scarcely noticeable to the occupants of the plane. Should the grapple or cable be fouled by an obstacle on the ground, a safety link in the cable will break, preventing any possible accident.

In present operations the pick-up load has been limited to 20 pounds, although loads up to 70 pounds have been successfully picked up in tests.

The mail bags used in this system have been so designed that they will trail smoothly in the air and also that they will withstand the shock of dropping at high speeds. As shown above, they consist of a smoothly rounded fiber nose with a rubber skirt attached and a mail container inside.

Looking toward the rear of the special airmail plane, showing a mail bag ready for delivery and, in background, the mechanical release operated by the pilot

Cancer's Mysterious Puzzle

"DUBLIC interest in the cancer problem is now at the highest point in history," says Dr. James Ewing, one of our foremost cancer experts and director of Memorial Hospital, New York City.

This interest is only natural. We have become aware that cancer is by far the most important public health problem. Some 150,000 die each year in the United States from this perhaps most mysterious of all man's afflictions. Cancer, it is true, is curable—to a certain extent, especially if caught in the early stages—and many are cured, or more accurately, are treated successfully; but the fact remains that many more are not cured.

The great mystery is nowhere near elucidationand on this point all experts agree. Why do some cells subtly begin to multiply aimlessly, to form an unorganized-bence cancerous-growth, which the body cannot control because the growth escapes from the unknown agents that normally keep all the tissues a unified harmony of structure and activities? Such is the problem, simply stated. Yet this simplicity is deceptive, for all man's enormous medical and bioknowledge is at a loss for the answer.

And so, any new clue to a possible answer is fascinating as well as distinctly promising. The discovery of substances which definitely have the power to induce cancer is the most promising of all recent leads—and

ing of all recent leads—and surely the most startling "One of the most fruitful lines of cancer research

in recent years has provided the demonstration that cancer may be produced at will in a majority of the animals treated, with a variety of chemical compounds. For the most part these compounds have been prepared synthetically and their molecular structure is known. They retain their activity undiminished after a high degree of purification. The cancers which may thus be induced experimentally are indistinguishable in their characteristics from the cancers which afflict mankind." So we are told by Dr. J. W. Cook, the English pioneer in the realm of cancer-

Though Science Still is Baffled by the Problem of Cancer's Cause and Cure, Research Continues... Most Alluring Leads of the More Recent Years

By BARCLAY MOON NEWMAN

inducing substances, who, with his coworkers at the Research Institute of the Cancer Hospital, London, has led the world in this line of research.

The story of the discovery of cancercausing chemicals begins at least as far back as 1775. In that year, the London surgeon, Percival Pott, re-

all thustrations courtery United States Public Health Service
Using the fluroscope with X rays in examination of the
chest for cancer. If there is a cancerous growth, a shadow
will be discernible on the screen in front of the other

marked on the prevalence of cancer among chimneysweeps and pounted out the probability. The soot is the significance of the probability of the soot of the significance of the soot of the

Later, other occupations besides the sweeping of chimneys were found to be plagued by significantly high rates of cancer. Skin cancer is frequent among workmen employed in the distillation of coal tar. Laborers who apread tar on roads; workers chronically exposed to shale oil and other lubricating oils, makers of certain dyes, particularly aniline dyes; spinners in continual contact with certain oils—in each of these occu-

pations we observe a suspiciously high cancer rateoccupational cancer.

N 1906, B. Fischer injected a dve known as Scarlet R into rabbit ears. The cells of the skin, after several injections, multiply abnormally, in a manner similar to cancer cells. But when these injections are stopped, cell proliferation ceases-that is, the growths are not malignant and so not truly cancerous. This work has been extended, and one outcome is the use of Scarlet R to hasten the healing of wounds. Another outcome, as we shall see, has led by a tortuous path into the field of true cancer.

In 1911, Peyton Rous discovered a chicken tumor which not only can be propagated indefinitely by transplantation from fowl to fowl—and hence a true cancer—but also can be induced by a mysterious agent or chemical extracted from

the malignant tissue. In these labors. Dr. Rous collaborated with James B. Murphy, now Director of Cancer Research, Rockefeller Institute.

As such facts were brought to light, a great question crystallized in the minds of cancer experts: Is a single substance involved—a lone fearful chemical which cause cancer? Great hopes, to, crose. Is the hypothetical chemical the sole cause of cancer Pariaps, it was speculated, the cause of cancer fact all, simple—and the cure likewise simple and near at hand. These hopes have been dashed. In their place, how

ever, are definite advances toward the vast secret.—for all that, the secret seems vaster than ever. Hope, if an inspiration to intelligent action, does bring results and newer, more firmly based aspiration.

In 1915, two Japanese ecientists, Yamagiwa and Itchikawa, set forth a fundamental experiment. They repeatedly applied coal tar to the ears of rabbits. Malignant growths developed Coal tar does indeed induce cancer. Yet coal tar is noted for the inestimably great variety of its components. To determine the guilty substance or substances would seem a herculean labor. Nevertheless, many investigators rushed to the task

A decade later, in 1924-1925, E. L. Kennaway, of the Research Institute of the Cancer Hospital, London, produced cancer-inducing tars in the laboratory in one matance by heating acceptance in an atmosphere of hydrogen under pressure. Then an ambitious program of detective work was plotted at the Institute—for Kennaway's discovery indicated the probable chemical nature of the cancer-inducing material. Acety-lene is a hydrocarbon, and the technici of the experiment apparently should yield only hydrocarbon derivatives of caetylene. Here was a pricelesse clue.

One by one, the known hydrocarbon constituents of coal tar were tried out on mice--a laborious procedure, involving months of work with each substance. Negative result followed negative result. The years began to go by All the known fractions were separately tested, in vain Still, the guilty agent was there in the tarry mixture-somewhere. A new conception of its potency arose. So rare, so difficult to find, the agent must be astoundingly potent in its action. Minute traces of it, beyond a doubt, could stir up a series of cellular changes having the fatal outcome of cancer

Y 1930, however, Mayneord and scopic technic by which it is possible to relate the spectra of tars and tar fractions with their cancer-inducing powers. Certain spectra, or wavelengths, were shown to be characteristic of the tarry materials exhibiting the maximum cancer-inducing activity. A special group of chemicals soon became suspect. This group is made up of the more complex compounds of hydrocarbons-known as the aromatic hydrocarbons, and known to feature rings of carbon atoms all tightly fastened together, and with hydrogen atoms clinging here and there; all to make up an intricate molecule.

Particularly suspect was the hydrocarbon called 1,2-benzanthracene, apparently not a cancer-inducing chemical itself, but a molecule giving rise, under the proper spectroscopic conditions, to wavelengths of light impressively similar to those from tars definitely potent cancer-inducers. A logical step was next taken. Why not try the effect of chemicals having molecular structures very much the same as that of 1,2-benzanthracene?

The detectives were able to write down the formulas of the chemicals

Treatment of a cancer with radium. During perhaps half an hour this treatment may continue, the patient feeling no particular sensation

most suspect. The substances were rather numerous and many had never tather numerous and many had never been seen. Dr. Cook rose to the occasion. He synthesized the desired undiscission. He synthesized the desired undiscission was the construction of the complexity of these many-ranged aromatic molecules. He also made available to this colleagues, by additional syntheses, the already discovered essential molecules.

As lack in science would have it, howver, the first cancer-inducing agent to be turned up was not among those hydrocarbons which Cook's originality enabled him to synthesize before any other chemist. This fact detracts nothing from Cook's extensive pioneering which has turned up dozens of cancer-inducing molecules.

Alert and co-operating remarkably, Kennaway, Mayneord, Hieger, and Cook in the course of their researches reached an utterly formidable molecule—also formidably named, 1,2,5,6dibenzanthracene. This substance they dealt with as they had with the others before. They dissolved it in benzene to make up a 0.3 percent solution. Twice a week they applied a drop to the skin of the backs of their mice. The weeks ran into months. Finally, in a large number of mice, small warts developed on the skin. The warts began to grow, many swiftly. Several frequently coalesced into a single horny mass, which, as autopsy proved, would push forth tentacle-like, hungry tissues extending down into the inner normal tissue.

When, in the future, history is written with the correct perspective, the year of this observation, 1932, no doubt will mark the start of a major epoch in man's effort to survive on his planet.

And, according to Howard B. Andervont, of the United Public Health Service and Harvard Medical School:
"This epochal observation, which was the outcome of a serves of brillhant experiments performed by the English workers, is an example of the results that may be obtained by co-operative efforts."

DR. Andervont adds: "It is also an example of the way in which observations made in the one field of science may lead to important advances in other, unrelated fields, for the chemists who first synthesized 1.2.5.6 dilhenzan-thracene were not interested in cancer research." In 1929, an organic chemist, Clar. had reported a new and ready means of making this compound, with which chemists had been familiar for some time

1.2.5.6-dibenzanthracene, however, soon lost its unique status-as the only known cancer-inducing molecule. Our Englishmen speedily found that 1,2benzanthracene also was cancer-producing, though only feebly so They identified the active constituent of coal tar in 1933: a chemical termed 1.2-benzopyrene. And, in the past few years, from their London laboratories has come a list of more than 30 chemicals clearly cancer-producing when painted on the skin of mice. All substances giving rise to occupational cancer contain a certain percentage of one or more of these agents or of their chemical kin.

Has the cause of human cancer been discovered at last? Not by any means. Dr. Cook states:

"We are not, of course, justified in inferring that human cancer is of chemical origin. All we can say is that there are a large number of experimental observations which are consistent with the view that the factor which initiates the onset of malignancy may in some cases be a chemical compound or compounds."

The very recent story of the developing science of cancer-inducing chemicals constitutes an amazing justification for Dr. Cook's judgment. The story really stupendous—it involves wholly unexpected relationships among life's highly diverse chemicals, relationships that are as profound as life's deepest secret. It appears that the enigma. What is life?, will as readily be solved as the enigma, What is cancer?

What mystery is deeper than that of sex? The discovery of some of the chemical messengers, the hormones, which play powerful rôles in the development of man and woman has only

made the mystery more involved-despite popular rumors to the contrary. have been united. Now workers in the United States become the pioneers. Edgar Allen, Professor of Anatomy at Yale University's School of Medicine, with Dr. E. A. Doisy, in 1923 showed that female sex hormone miections can start certain tissues growing with astonishing rapidity. Also at Yale, and collaborating with Dr Allen, other investigators-G. M. Smith, W. U. Gardner, L. C. Strong, and W. O. Nelsonhave advanced far along these lines. The English school has reciprocated by establishing that some of the known cancer-inducing chemicals can, in special cases, act upon the body in the very same way as certain sex hormones!

LACASSAGNE was the first to report (1932) the production of true cancer by use of sex hormone. Mammary tumous developed in male mice after a lengthy series of injections of estrin, a female sex hormone. Large doses are required.

"This is a very significant observation," says Dr. Carl Voegtlin, Chief of the National Cancer Institute, United States Public Health Service, "since Little reports that in over 5000 mice in his colony spontaneous mammary tumors occurred only in the females and not ma single male."

Incidentally, the males take on certain female characteristics—and, like true cancers, the mammary growths can be transplanted from the femmized males to either males or females. The cancers, Dr. Allen and his co-workers inform us, after transplantation will continue to grow without additional stimulation (by injection of more hormone). Hence, we must not forget, the genetic or hereditary factor may always play a part in cancer, however induced. This consideration is a whole seence in itself—another imposing history, fascinating too.

Not only mice respond to sex hormone injections Such injections produce abnormal growths in rats, guinea pigs, monkeys. Some of these growths are typical cancers. Recently, the American Medical Association warned against the use of a certain cosmetic containing female sex hormone and pointed out the possible production of cancer by repeated application of the cream. The Association has also warned against promiscuous injections of female sex hormone in therapeutic measures. There is no doubt that human beings would ultimately develop malignant growths subsequent to long-continued treatment with such chemicals. Clinical results-in which non-malignant growths have begun to show up just before treatment was halted-confirm these forebodings. (The non-malignant growths cease development and generally recede harmlessly enough upon cessation of administration of hormone.) Where the unified investigations of sex and cancer will lead, noncan predict. The future is unimaginably stret.

There is a strikingly close resemblance between sex hormones and the particular cancer-inducing hydrocarbons dis-

The X ray in action for treatment of stomach cancer, 1,000,000 volts now being used to get deep penetration, also to minimize skin burn

covered by the English scientists Some of the cancer-producing compounds have hormone-like activity. Other physiologically active chemicals—in-cluding vitamin D—have molecular structures also strikingly like cancer-causing chemicals.

And so, naturally, there has arisen a theory that, in some weird fashion, the normal course of chemical transformations within the tissues may be upset and, out of an essential hormone or allied chemical, cancer-producing chemicals may disastrously emerge. This theory is still, for all its apparent plausibility, little more than a guest

Yet there are other lines of approach to the problem and they suggest the toe problem. One of the most powerful cancer producing substances is methyl-cholanthere. One of the acids found in bile has a cancer producing substances is methyl-cholanthere in one of the acids found in bile has a cancer producing molecule. The biochemist addy makes methyl-cholanthere from bile acid—why may not the distraint such such as the producing with the such acids of the truth.

There is even more to puzzle us—in fact, tremendously much more. A war, like substance, cholesterol, is present in every cell of the human body; bram and other nervous tissue are especially rich in this chemical. Cholesterol is a member of the chemical family—of related or closely similar molecular structures—to which hile acade, sex hor-

monea, and cancer-inducing chemicals belong. Now to this group of almost belongs. Now to this group of almost an inquely strange things we must addate the control of the c

Four Japanese scientists-Yoshida, Otsuka, Nagao, and Kinosito-have made outstanding contributions to cancer lore. Their successes too, nevertheless, have served only to increase the entire mystery. Yoshida demonstrated that the Scarlet R molecule, used to accelerate the healing of wounds, can be burst to yield a cancer-producing molecule, which he identified. In a sense, it was disappointing to learn that this carcinogen is not a hydrocarbon-and so is not a member of the family of the carcinogenic hydrocarbons. The future would have looked much brighter if nature had decreed that only one general type of chemical can be cancerproducing. Many utterly different classes of molecules possess the dire potency

IN fact, the so-called "azo compound" of Yeshida does not induce malignant growth of the skin where repeatedly applicable of the state of the state

Startlingly enough, Kinosita has shown that "butter yellow," a dye hitherto useful in coloring butter and other foods and similar in chemical structure to Yoshida's carcinogen, induces liver tumors in rats. Presumably, butter yellow is dangerous; hence its use in foods has been discontinued.

Today more than 50 different cancerproducing chemicals are known. Is there any property common to them all—besides, of course, their carcinogenic activity? No. And we can be sure that, in the gloomy light of the measurcless dread of cancer, every conceivable property has been considered.

Is there any indication of how these substances produce cancer? No.

In a recent lecture subsequently published in Science, Dr. Carl Voegtlin gives us the conservative, present conclusion: "It seems wiser for the present to admit our ignorance concerning the mode of action of carcinogenic agents."

Man – Mechanical Misfit

In the Long Course of Organic Evolution Diverse Experiments Have Been Tried, Some Successfully and Some Not . . . Is Man Destined to Failure?

By G. H. ESTABROOKS

TATURE is not infallible Far from it. She blunders along for a trifling 300,000,000 years to produce a gigantic race of dinosaurs-then scraps the lot She puts in another 100,000,000 perfecting a type of mammal that makes the elephant look like a pygmy. Then, in a huff, she packs him off bag and baggage to the realm of fossils. The last 20,000,000 years she has been specializing on man and his ancestors. There are many of us who feel that she is just on the verge of losing her temper with this latest product. It may be a guilty conscience, but at times she seems to send in our direction what can only be described as a very dirty look.

However, we are not interested here in eccounting the story of evolution. Rather we wish to draw attention to certain engering problems with which nature found herself confronted. The production even of man is a tremendous feat, for the engineer builds with only one type of brick, the cell; and there are many billions of these in the human body. To be sure, they differ much from one another in form and function in size, from which nature finally constructs such monsters as whales, elephants, or

Let us take a very brief glance at the nature of the animal. Fundamentally he is just a gasoline-carbon-burning engine and its basic problems are few in number. When carbon burns it simply unites with oxygen, produces energy in the form of heat and leaves certain waste products behind. So nature's great problem in building an animal-engine really subdivides into three smaller posers. First, get the carbon (food) to the engine. Second, guarantee a source of oxygen and, third, remove the waste. Three neat little problems on which nature has been working for 2,000,000,000 years and is just getting warmed up, so to speak. Of course, there are minor considerations as well. She has spent a great deal of time and energy perfecting the machine, as such. Also she has had to devote much "thought" to its protection, for some animals find the the easiest

possible way to collect a supply of food is just to eat up the fellow next door Not all these problems have been of equal difficulty. At times we can see where the whole course of evolution has been held up for one or two hundred million years while nature's experts were trying to invent a suitable carbureter. or were completely changing the ventilating system. The fuel pump (heart) has caused no end of worry and the exhaust system (kidneys) is continually causing labor trouble. Yet, for all that, the machine runs and probably will be running hundreds of millions of years from now

TAKE the question of the fuel supply. Difficult, to be sure, but not as serious as some of the others. Nature's first animals were tiny microscopic blobs of protoplasm The ameba is a giant compared with these first attempts, but if we put it under our microscope we find that its food problem is simple. Its body literally flows around a particle of food, which then passes right through the body wall into the body itself and is there absorbed into the tissues. None of this nonsense about stomachs, mouths, livers, or such things. But life became more complex and, even in these singlecelled animals, we soon find a definite "mouth" appearing and a stomachreally a food sac. For hundreds of millions of years nature was quite satisfied with this arrangement. The animal took in food through a definite opening, digested it in this food sac, and then expelled the waste through the same opening. The sea anemone with its waving tentacles is an excellent example of this stage in the food question, although this method applies also to much larger creatures such as the jelly fish and the Portugese Man-of-War. But it was inefficient, especially when we came to larger animals.

Much more practical was the continuous digestive tube which nature first brought in with the roundworm and has used for the past 700,000,000 years in all higher models. Here the food comes in at one end of the body and follows a

continuous course until the waste is expelled from the other extremity. This is one-way traffic and nature could then add livers, kidney, bile ducts, and various types of glands all along the passage, guaranteeing the proper digestion of the food, the elimination of waste, and no worry about congestion caused by back traffic.

This matter of getting food in and waste out of the whole body was not such a serious problem. Somewhat more of a poser was the question of distributing the food, once it was within the body walls. In very tiny organisms nature trusted to the principle of diffusion: the digested food would leak through from one cell to the other. But this had very definite limits. As the animals grew larger she tried the idea of side tubes going out from the central stomach These would convey food to distant parts of the body and then diffusion could get in its work. This idea was better but also called for improvement. In anything larger than a small worm it did not give satisfaction, especially in so far as waste products were concerned. So nature took a tremendous step and installed a fuel pump (the heart) which forces the food in under pressure and literally washes out the debris.

This fuel pump and the fuel lines (blood yeasels) have been a continual point of worry to Mother Nature, with continuous alteration in design. The earthworm has half a dozen of these hearts, which are really only thickened and muscular atteries. Since then, has the continuous after the continuous continuous

The matter of getting food into and through the body was, however, simple compared with the problems involved in the oxygen supply. Carbon is worthless as a source of energy unless an adequate supply of oxygen is always on hand, but how to get it into the body and then guarantee that each of the billion cells would get its share? All life started in the water and there is plenty of oxygen dissolved in normal water supplies. Nature's first answer was again to depend on the principle of diffusion. Gases or liquids will always tend to equalize pressure, if possible. There is less oxygen in a cell than in the surrounding water, so the oxygen in the water, because of its greater concentration, is pushed through the very thin cell wall into the cell itself. Once inside, it unites with carbon compounds, forming the gas carbon dioxide, CO,. This is in much greater concentration within the cell than in the surrounding water, so the CO₂ is pushed out again—a very neat little arrangement whereby the cell in question is assured of an adequate supply of oxygen.

However, this principle has very definite limitations. The cell or body wall must always be moist and must be very thin, otherwise this exchange of oxygen and carbon dioxide will be so hampered as to be inadequate for the needs of the animal in question. An animal the size of even a small fish needs such a thick skin to hold it together that diffusion is impossible, so nature found herself inadequate of the control of the conlution until she could answer this problem of oxygen supply.

Here nature showed real genius. She already had installed a fuel pump in these primitive animals, which guaranteed a supply of blood-carried food to every last cell. Why not use this same pipe line system to get the oxygen around? Only how? The answer was hemoglobin, a red iron compound which colors your blood. This substance has the peculiar power of forming a very unstable alliance with oxygen. As it passes through your lungs, forced on by the heart pressure, it takes on a load of oxygen and then literally dumps it at whatever cell has the greatest need-that is, the least oxygen pressure. Only, of course, at this stage in the game nature hadn't even thought of lungs. All life was in the water. Lungs were several hundred million years away.

O nature handed this task of oxygen So nature nanuou to the blood stream, in addition to its already important one of transporting food. In some relatively late models, such as the insect, the blood still has no responsibility so far as oxygen is concerned. In nature's improved model it had; but how was she to get the oxygen in the water to make contact with the blood stream? After much fussing about with her old idea of skin diffusion she hit on the gill slit. Here the water flows through the gills of the fish or other water animal, propelled by the throat muscles of the species in question. In these gill slits, as you can see by examining any fish, the blood comes very close to the surface of the body, being separated from the water only by the thinnest of skins. Here we again have the principle of diffusion. The oxygen is forced in through this skin because of its greater concentration in the water and the carbon dioxide is forced out for the opposite reason, thus guaranteeing an adequate supply of oxygen in the blood stream which transports it to the individual cells. The gill slits are the lungs of the fish, and nature was now able to proceed with evolution, having solved a major mechanical difficulty. Size was no longer restricted by this question of oxygen supply, formerly a limitation. But increase in size immediately raised another question. You can't have rained annuals 30 feet long which are just annuals 30 feet long which hare just masses of jelly; you must have some form of girder on which to drape this mass of muscle, tissue, and blood Obviously, hone of some sort was the answer. But given hone, then what? Should the skeleton be inside or outside the

THE reader will note that, in the accompanying article, the author personifies nature: na-ture thinks, nature makes plans, nature rejects, and so on. The reader is at liberty to take this literally or he may regard i more as a convenient manner speaking. Since the time of Darwin the great majority of scien tists deny outside planning and ascribe the amazingly intricate fitting of parts as the result of millions of years of slow ac-cumulation of useful combinations. Every organism has the power to make certain adjustments to changes in the environment. It also has the power of adjusting itself while it grows Organisms also vary from time to time with regard to particular features. Give this variable, adjustable organism, say, 50,-000,000 years and the fossil evidence shows that sometimes (not always) it does take advantage of new opportunities and does advance with the times Other types remain more fixed and stable than the mountains. The author, in his article, selects a few of the hundreds of forms known to science and shows what happened to those that did advance from fish to

Will nature really discipline man? Or will social man with his superior adaptability recognise and head it off? Just at present he is demonstrating (is Europe) the need of the slipper. Is he corrigible? Who know?—The Editor.

water animal in question? This question was so vexing to nature that she did it both ways and then sat back to watch results—is still watching results, in fact very critically, for if man is chased off this earth the insect may do the job, and the insect has the outside skeleton.

This external skeleton has two tremendous advantages. Physical strength is a question of attachment area for the muscles and the external skeleton affords protection. The lobster tribe and many insects are incased in a shell which is "proof" to animals at their own level.

But, opposed to these advantages, is the problem of weight. If this casing is to be effective, then the animal is slowed up by its weight despite its extra strength. It is like the knight of old without his horse, or the heavyweight wrestler-dangerous customers if they can get you cornered, but not much of a problem if you take to your heels. And nature has discovered that the very best of all protection is speed. A hawk is dangerous to a sparrow but a swallow doesn't even notice him. Both hawk and swallow know he'd be wasting his time if he started on a race. Here many insects have hit a very neat compromise. They cut down the weight of the external skeleton to a minimum and while they lose its protection, they still retain the great advantage of the additional strength. The result is tremendous speed of movement. But the insect can attain no great size, because of a very primitive oxygen supply system—just a number of tubes or trachea going into the body from the outside air.

So nature discovered that if she wanted size—and apparently she too is imbued with this "bigger and better" idea—she had to have an internal skeleton and a device for guaranteeing an adequate supply of oxygen, such as in the case of the shark. As a matter of fact, the shark is one of our very oldest succion.

But here, as elsewhere, the solution of one problem only led to another. All animal life up to this present had probably been in the water, but there was a lot of dry land and plenty of plant life on itwhy not invade? Only how? Once again that miserable question of oxygen supply held up the whole course of evolution. So nature handed this problem of an air-breathing land animal over to her research staff. Many and interesting were the early models. We have fishes which will drown in water, such as the Siamese fighting fish-it breathes air. Other fishes can leave the water and climb trees by means of their stiff fins. They take a deep breath, so to speak, in the water, close up the gills and hold it for ten minutes while on the land. Then we have a lung fish which can breathe in air when its pool dries up in the summer, but which much prefers water. We even have certain land animals-some salamanders-without lungs. They just gulp air into the throat and from there the oxygen diffuses into the blood stream.

NATURE'S ultimate answer was, of course, the lung. Originally this was probably the air bladder with which many fishes are equipped and whose duty it is to regulate the creature's buoyancy in water. If he wishes to come up he inflates the bladder, and vice versariust like an army blimp. Some type of primitive lung fishes got the knack of gulping air into this bladder from the atmosphere. Then the oxygen diffused through the thin walls into the blodd through the thin walls into the blood

stream and we had our first air-breathing

We have come a long way from this primitive apparatus, however. The efficiency of your lung depends on the area of contact over which blood and air can come close enough to insure diffusion. The greater the area the more oxygen can pass into the blood stream. It is self evident that you would greatly increase the internal surface area of a simple bladder-say, a football-if you jammed it full of wrinkled tissue paper. The more you crinkled the paper and the more you crowded it in, the more surface of contact there would be-always supposing that you have enough room left for very tiny blood vessels and air tubes to traverse the whole mass of paper. This was nature's trick to improve the lung Whereas the outside surface of your lungs is 16 square feet, so expert was nature at this crinkling process that the actual internal surface of contact is about 170,000 square feet, or over 10,000 times as great. So well has nature supplied you, that large areas of your lungs are relatively inactive. You can, in case of accident or tuberculosis, get along very nicely on one lung, or even part of a lung-provided you don't want to play football and race the engine.

O nature developed the lung and got an animal which could live on dry land. For the first hundred million years he put in the early part of his life in the water, as does the present-day frog. Then the race of true reptiles came along, laving their eggs on land, and so the true land-living species developed. But, before developing these land animals, nature found herself up against another engineering problem-that of locomotion. How were these animals to move? Evolved, as they were, from fishes, nature did not have much to go on, for a fish is pretty helpless on dry land.

But never be it said that nature sidestepped a problem. She took the four man fins of the fah, two in front, two behind, and resolutely set out to develop lega. This idea seems very simple to us today, but the nearest approach nature had arrived at which could be adapted to land use was the single large foot, best seen in the case of the snail. This guarantees progress, but not much progress.

In fact, now that nature had produced a land animal, capable of large size and fast movement, she did exactly what the human being always does in the enthusiasm of youthful ignorance: she overdeveloped and overproduced. Dinosurs-repitles—came from the factory weighing up to 40 tons (your largest elephant weighs only ten tons), some of the carnivorous varieties being the fiercest beasts of prey the world has ever seen. The repitles-rinvaded the sea and produced literal gas serpents. They even

sprouted wings, a-là-bat, and gave us the largest, fastest, and fiercest natural inhabitants of the air yet to be seen.

In fact, the repitles run the world. For from two to three handred dillion years this world wasn't safe for even noother repitle unless the could move very fast or was so luge and well protected that even these big bullies didn't dara attack him. Then, just when their rule seemed absolutely undisputed, nature wiped out the whole lot and turned to another model.

For some reason or other, nature had also manufactured these repulses with a minimum of brams. Even the largest of them had a brain no bigger than your fat. They must have been extremely stupid despite their size and fercreness Nature has since been producing models with more and more brain.

But the real weakness of these reptiles which probably led to extinction was the fact of their being cold-blooded animals. This carbon-burning engine which we call our body as exactly like your auto or many respects: it won't go if it's too cold and it atops if it heats up below and certain point. The cold-blooded animal is at the mercy of the temperature, As the thermometer approaches freezing he becomes aluggish, and at freezing weather the meachine samply stops. The same applies when the temperature goes too high.

So nature evolved another model, the so-called mammal. She gave him a cost of fur to keep out the cold-or heatthen arranged an internal combustion system which works always so that the engine is continually warmed up. Not only that, but, in every species of mammals, she established an automatic thermostat. The human engine works best at 98.6 degrees. Any variation by as much as one half of one degree is a signal of engine trouble and for the services of a mechanic-no disrespect intended to the doctor. Just to make a good 10b of it, nature established the same mechanism in the newly evolving race of birds. Then she stood by to watch results.

The new machine proved its superivity in decisive fashion. Very soon the mammals and birds ruled the roost just as ruthleastly as had the reptiles. Then nature repeated the rold mistake—bigger and better, but bigger at any cost. She developed mammals, such as the long extinct "thunder beast," Baluchither-time, of Asas, far larger than the largest elephant. And once again she wiped out the lot.

The trouble with these huge brutes was one of food supply. Every so often climatic changes occur which cause huge areas of the earth to become semi-desert in nature. If we had a severe drought in the western plains for five years, a mouse or a rabbit might survive: for after all, he only needs a leaf.

or two and somewhere or other that seant might die by the millions but enough of them would survive to perpetuate the species, once the hard tumes had passed; but an elephant needs a bale of hay per meal, and that is something totally different. When drought conditions arrive, the big anmais suffer most. And, if the climate changes, as it has in the glacial epochs when huge areas of the world were covered by ice, all animals are iliable to extinction that cannot adapt themselves to a cold climate or to a hot climate, when the ice fields retreat.

So nature produced her latest model, man. She had learned that even her highly elaborate heat-conditioned mammal had its weaknesses, but she had also found that one of its most advertised features, namely, its brain, seemed really to be of survival value. In modern man she staked nearly everything on brains; for, as a machine, he is a joke His naked skin gives absolutely no protection against the weather He can't run rapidly; a tiger can eatch him m a twinkle And by himself he can't fight; any carnivorous beast his own weight can serve him no as breakfast to the cubs.

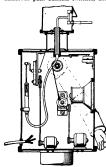

Though early man was much tougher than modern man, his best hope was his wits. Cornered, he seized a stick, and found his first club. One day he threw the stick and invented the spear. When he glaciers crept down he wrapped himself in a buffalo skin and discovered clothes. Somewhere he stumbled across fire. With skins, fire, and some sort of shelter he could let the blizzards blizzari fihe didn't starve to death. But he didn't. He got the run of the seasons and learned to store food when the hunting was good against the lean winter period

THIS last child of nature became literally a brain child. It has long been a commonplace of parental experience that bright children may need a little discipline, and it seems to many of us that nature is now reaching for the shpper. Her grievances are many but may be summed up in one major charge: man is using his brains to eliminate the fit and to perpetuate the unfit. To qualify as cannon fodder in this 20th Century you must be a physically perfect specimen; while the others live on. Also, we have learned tricks which give us our present differential birth rate, a system which restricts birth in the upper classes, and this may easily yield us a "moronoc-

Any attempt to peer into the next million years merely impresses us with our own ignorance. We can say only that nature, after spending vast periods of time in developing a perfect machine—witness the cat—seems to have made a departure in the case of man. He is a mechanical misfit.

Automaton Salesmen

A UTOMATONS have been constructed by many engineers, in bodies that mimic those of human beings, but these have usually been for exhibition purposes and have been complex mechanisms of wires, photo-electric cells, and other special devices such as numerous push buttons, switches, and

Mechanism of one of the earlier mechanical men, the basic features being typical of many of the designs

relays. Decidedly, they have not been of the type that an advertising department would purchase in quantities for merchandising demonstrations. Automa tons to promote sales are, however, now available from a recently formed corporation. They are covered by patents.

Mechanical Man, Inc., will make a figure to advertise any product by attracting the fascinated interest of the multitudes and thereby impressing upon them the particular trade name. More important, the figure may be made, out-

The penguin (top) puffs contentedly on a lighted cigarette, winks, and moves filppers and head. The girl drum major spins her batons and executes graceful movements

men" is their chief point of interest for the technical man. Their simplicity is, furthermore, most surprising. In all cases—whether the figure be small or large—all the action is powered by a fractional horsepower electric motor. Reciprocating movement of parts of the body is accompliabed by rod linkages between disk driven by worm gears or pulleys. Adaptations of this simple principle give the designers an endless variety of possible combinations. A simple pump with a crank-operated pison supplies the suction, through a small tube, for puffing a cigarette.

ANTHRACITE ASH IMPROVES SOIL

PENNSYLVANIA anthracite ash has long been used to improve soils, but exact scientific data on such utilization were made available for the first time only recently. Compiling results of experiments conducted at the Mellon Institute of Industrial Research by the Multiple Industrial Fellowship in Anthracite, a booklet just published by Anthracite Industries, Inc., shows that Pennsylvania anthracite ash has at least hve advantages for gardening use in im-proving heavy soils alone, namely improved texture and workability of soil, better moisture absorption, reduction of erosion; improved drainage and acration; and increased resistance to drought conditions

"Since anthracite ashes are of a mineral nature," the booklet points out, "their bene-ficial effect is permanent. In this respect they are superior to humus or other organic materials which tend to disappear from the soil in several years' time. A still further advantage is that humus and soil-conditioning materials are expensive, while Pennsylvania anthracite ashes are readily available

Contributing Editor ALEXANDER KLEMIN

In charge, Daniel Guggenheim School of Aeronautics, New York University

in the anthracite heated home at no cost." Suggestions for the improvement of lawn or garden soils are given, both as to amounts and methods of application of the ash, with outlines of procedure for the more scientifically minded or professional gardener for conducting his own experiments. Descriptions of additional uses are also given, in cluding utilization as a summer mulch, for underdrainage, for making compost, for soilless culture, even for growing rhubarb in the basement during the winter months.

Telescope Museum

WHEN the Corning Glass Works cast the W first of the 200-inch blanks for the gigantic telescope on Mount Palomar, California, some of the cores with which the under side was to be honeycombed floated

out of place and made it necessary for a new blank to be cast. Because this great disk was the first such enormous casting in glass in the world, a stream of visitors was continually passing through the plant to see it, and it was finally decided to install this blank in a museum of its own in the city of Corning. Accordingly, a structure resembling a miniature observatory has been built in the Corning City Square, and by this time the blank will have been installed as

a permanent exhibit So gigantic is this "sky eve"—17 feet in diameter and 20 tons in weight-that it was found necessary to build a special carriage for transporting it. An accompanying illustration shows the disk being transported through the city of Corning to its permanent museum. In this picture is clearly shown the imperfect honeycomb of its base.

Water Soluble Resin

SYNTHETIC resin which is insoluble in organic solvents but soluble in water, acids, alkalies, and salt solutions has recently been announced. It is film-forming when deposited from aqueous or water-solvent solution. The resin, Rhotex A-20, is recommended by the manufacturers as a water soluble thickener; a solvent resistant coating; a sizing, emulsifying, and dispers-ing agent, or a clear, colorless film base.

CANCER MAY BE CAUSED BY VIRUSES

ANCER, at least of certain types, is caused by filterable viruses, and thereby joins a numerous and varied group of human ills including smallpox, influenza, and infantile paralysis Such is the conclusion toward which points the evidence pre-sented by Drs. James B. Murphy and Albert Claude of the Rockefeller Institute for Medical Research, by Drs. Jacob Furth and Elvin A. Kabat of the Cornell University Medical College, and by Dr. F. Duran-Reynals of Yale University.

Fluids from malignant transplantable tu mors of chickens were whirled in the ultracentrifuge, passed through fine-pored filters, and otherwise treated after the manner of virus-containing fluids in known animal and plant diseases. Materials obtained from these cancer-fluid filtrates, injected into the tissues of healthy chickens, produced typical cancerous growths.

Moving the giant telescope mirror blank to its museum

Official photographs, Ordnance Department, U. S. army

The 155mm field gun being towed by a track-laying truck

is heavy traffic

In the researches reported by Dr. Duran-Reynals, chicks responded to doses of a tumor wines by developing fatal hemorrhages and degeneration of tissues, without the development of tumors. However, extracts obtained from such chicks produced the characteristic growths when injected into healthy adult fowls—Science Service.

LONGEST-RANGE

FIELD GUN

THE United States now has a field gun which has fired a projectile farther than any other standard field gun has ever been fired. Of 155mm caliber, it sends a projectile a distance of 25,000 yards or, roughly, 14 miles, and blasts a hole in ordinary ground 16 feet deep. It has been named the 155mm gun, MI

Development of this gun grew out of a need seen in the World War, particularly at about the time of the first battle of the Marne The noted French artilleryman, General Herr, wrote of the difficulties the French had in retreating under the heavy fire of German guns with no guns which could answer in kind They needed artillery of very long range which could remain far behind the lines and yet paralyze the enemy and harm their morale This would be done by insistent shelling of the main roads of enemy approach, important stations, ammu nition depots, and centers of distribution, and by making their headquarters unten-able and demolishing points of observation. Further, these guns were found necessary for bombarding the enemy's roads of retreat, their reserve stations, and supply dumps of all kinds This kind of fire was called interdiction fire.

Hence, there was a demand by the Caliber Board of the United States Army for a gun of about caliber 155mm, with a vertical arc of fire from 0 degrees to plus 65 degrees; a horizontal arc of fire of 360 degrees; a projectile weighing not over 100 pounds; an maximum speed of 12 miles per hour; and

a width and maneuverability which would permit its use on highways on which there

The 15Smm gun has met most of these requirements 18 to weight exceeds the weight limit by 28 percent, as it is slightly over 55 tons 18 to vertall width is about 99 inches which is somewhat too wide for rapid movement in two-way traffic. On anything but and width provide a severe handicap, Despite these factors, it is an extremely efficient weapon. In action, it will not be called upon to make long forced marches but will be used as our principal instrument for reaching the long-range targets mentioned above. It will, of course, be as mentioned above it will, of course, be as the contract of the con

This new gun is mounted on a six wheel bogie with rubber tires and in the firing position will be lowered to a firm position made by spreading the outrigger spades.

JUMBO CANAL-WALL

TRIMMER

THE fourth and last section of the great "Yakıma Project" is now far advanced—a system of canals, tunnels, flumes, and siphons which will eventually irrigate

72,000 acres of farm land in central Washington Many miles of this project will be causals of an open "V" shape with concreted walls and beds. To expedite the concreting job, the sides and bed were trimmed by a unique traveling machine developed in the shops of the H. J. Adler Construction

This new trummer rides on a single rail on each canal bank. It is powered by three Ford motors—one on each bank, and the third for the belt conveyor which is loaded by a centrally located bucket elevator. The entire trimmer advances at the rate of a foot and a half a minute.

The sides of the "\" are two 17400 rollers, attoded with hundred to small prorollers, attoded with hundred to small proposing teeth or puss. As these rollers, which are made of 12 nuch heavy-duty pipe, are moved along the slopes of the canal, the spirally-set tech engage every such of the surface and shear is smoothly. The shear ing is so complete that no overduging or back-filling are required, and fine grading can be done at a fraction of the usual cost.

EXPLOSIVES

IN the past 12 years, American and Canadian railroads have transported millions of tons of high explosives without death or injury to suyone.

WASTE

Company.

AT one of the symposis of the recent meeting of the American Chemical Society were discussed some of the more important of the large number of instances where industrial or trade wastes have been converted through research into raw metrajals for the manufacture of commercial products it was stressed that differentiation must be made between hyperducts in the usual sense and materials which are rure weater sense and materials which are rure weater sense and materials which are rure weater pense for their satisfactory disposition. Under this latter classification may be

Under this latter classification may be included the manufacture of sulfaric acid and recovery of elemental sulfar from smelter gases, the production of sulfuric

Traveling canal-wall trimmer that rides on rails

scid from the hydrogen sulfide in petroleum still gases, and the recovery of hy-product sulfur from the hydrogen sulfide in illuminating gas. Sulfite waste liquor has become the source of vanillin and a number of other products.

Waste casein finds its way into resins and adhesives; the fermentation residues in the alcohol industry have been converted into cattle foods and the carbon diouxed into the foods and the carbon diouxed into the comment of the comment industry, and building blocks have been made from the fit sah.

In a sense, the long list of solvents now recovered from gases derived from petroleam represents success in the use of othervise water materials. The same may be said of cements made from blast furnace aleg, and synthetic methanol unlies carbon monoxide present as an interfering substance in gases used in the fixation of nitro description of the same properties of the from bagases are other examples of this type of materials.

LINENS

THE Pullman Company 18 sometimes called the world's greatest housekeeper. In one year it purchased 220,528 sheets, 157,780 pillow cases, 20,253 tidies, 455,829 hand towels, 24,318 headrest covers, 13,692 napkins, and 3260 table cloths.

CHLORINATED RUBBER

F further proof is needed that American engineers and chemists are equal to or better than European techniciscus to be found in a recent issue of Chemical & Metallurgrad Engineering, James A Lee, witting in that magazine, states that in the few years succe securing the rights to produce chlorinated rubber in this country, Hercules Powder Company chemists and regimers have improved the originated rubber in the improved the originated rubber in the country, margineers have improved the originated rubber in the improved the originated rubber in the improved the originated rubber to the improved the originated rubber to the transition of Europe.

VINYON, IMPORTANT SYNTHETIC FIBER

ANOTHER synthetic resin fiber, that can be turned into lustrous silk-rivaling hosiery, has just been announced. Known

A be turned into lustrous silk-rivaling hosiery, has just been announced. Known as polyvinyl acetal reain, the new fibers are further cause for headaches among the Japanese for they are synthetic, made-in-America rivals for Japane's natural silk. Silk is the largest single export of Nippon to Uncle Sam.

A research team of Carbide and Carbon Chemicals Corporation, including Harold F. Robertson, Edward W. Rugeley, Theophilus A. Field, Jr., John F. Conlon, C. O. Young, and S. D. Doulgas, has been busily pliing up patent after patent on this achievement.

Polyviayl acetal resin can be produced in fibers as fine an natural silk, virtually as strong, more elastic, waterproof, and fireproof. The basic materials of the tervest fibers are salt, coal, lime, and sir. Out of these cheap and plentiful raw materials are made high molecular weight (7000 to 13,000) water-player resins. The actual production consists of polymerizing vinyl halides with virty sters. Among the suggested uses of the new proof clothing, bathing units, frieproof and ing which are interpreted coloning, bathing units, frieproof awning which are still-like in appearance, fishing lines, fishing note and seines, acid and skill-resistant clothing, electrical insulation, and curtains for shower baths. The wife branterial, to be known as Vinyon, is not yet in commercial production for honeary. In the properties, it is comparable with nylon, developed and by a different chemical method—Science Series.

BIGGEST BUTTER

MAKER

THE largest churn in the country has just been built by the Jennen Croamery Machinery Company, Oakland, California, and installed in the Challenge Cream and Butter Association plant in that city. It is constructed from two sand-cast aluminum shells which, together, weigh 1500 pounds In tests, this unit has churned 660 gallons of cream into 2580 pounds of butter

Batches of 2580 pounds of butter are made in this aluminum churn

m 30 to 45 minutes Because of the cubical design, the churn is reported to be capable of churning butter in 50 percent less time than the conventional roll type units.

The huge aluminum castings which make up to be down this new dairy machine were cast at the Los Angeles foundry of the Aluminum Company of America, and are among on the largest aluminum castings ever made. The patterns were no large that special doors had to be built in order to move them out of the pattern shop into the foundry for casting. Aluminum was used in the construction of this churr in order to obtain the advantages of the metal's lightness and non-contaminating properties.

NEW REFRACTOMETER

A SIMPLE instrument for measuring the refractive index of glass has been devised by Frank Benford of the General Electric Research Laboratory. Though smaller and much less costly than previous instruments, the new refractometer is accurate to two decimal places. The principal parts of the device are a telescope, mounted like a microscope, and a pollshed metal prism. One surface of the latter is vertical

Refractometer and its telescope

and another is at an angle of 45 degrees from the axis of the telescope.

As the angle of till is fixed at 45 degrees by the prism, only the thickness of the glass and the amount of displacement of an object viewed through it need to be measured The thickness is measured by placing the sample against the vertical face and taking comparator readings.

Attached to the filled surface of the prism as a pace of drawing paper on which a large dot has been made with black int. Displacement is measured by adjusting the base until the cross-hair of the telescope is tambush the set glass. The difference is the through the test glass. The difference is the optical displacement. With this datum, the index of refraction can be determined by slide rule and reference to table.

For the study of thick glass, the use of a sodium lamp as an illuminant has been found advantageous.

PHOSPHATASE TEST

MADE ELECTRICALLY

ANOTHER step in making milk safe for public consumption is taken by the Luximeter, a new instrument developed by the General Electric Company to check the degree of pasteurization of milk by the phosphatase test.

A chemical test for determining the de-

Milk undergoing phosphatase test

A truck is used for transporting the radio-controlled target plane to and from the anti-aircraft range

gree of pastrursation has been used for the last few years with great success in the Sandhavian countries, and the New York State Department of Public Health has been among the first in this country to experiment with this method of making the phosphatase test. General Electric has been working in close Collaboration with the New York State Department of Public Health for the last year and much valuable data and

suggestions have resulted from the efforts of the Health Department.

The G-E Luxmeter, while designed primarily for use in measuring the transmission of the blue solution obtained in the phosphatase test for milk, has many other possible applications. One use in particular to which it may be readily applied is that of making a turbuidty test in water supplies. Satisfactory turbuidty measurements have been made over the range of 100 to 3500 parts per million on the silics scale.

The new instrument consists of a lightsource, a light-sensitive cell, and an indicating instrument, all in one compact unit. The light source is regulated by a rhoostat and is directed through a glass tube containing the solution to be measured. The light so transmitted falls on the sensitive surface of the cell where the values are read directly

in percentages on a micro-ammeter Requiring only a six-volt, half-ampere power supply, the Luximeter may be attached to a storage or dry hattery, or roltage regulating transformer. The new instrument weighs only two pounds. It may be carried about by milk inspectors on their tours of dairies or used by large dairy owners in testing their pasteurization.

PHOTS

BY the end of 1941, Robert H. Hinckley, Chairman of the Civil Aeronautics Authority, predicts that the United States will have a total of 70,000 licensed pilots.

RADIO CONTROLLED

TARGET AIRPLANE

POR training infantry and field and coast Fartillery in anti-aircraft gunnery, targets are frequently towed behind an airplane which flies at a relatively low height. These targets are of the sleeve type, resembling the wind socks seen at most airports.

Towing sleeve type targets has many dis-

the small air-cooled engine of the target plane is started and adjusted to the required revolutions per minute. A catapult shoots the airplane into the air; and flight is maintained by two small propellers driven by the single engine. These propellers rotate in the single engine. These propellers rotate in stream effects are climitated. When, the serial target has completed its mission and given the ground personnel sufficient practice for the day, the operator directs the little craft to a landing area. He then presses a button; immediately the moore stops and a button; immediately the moore stops and inaget losis sently to the ground and is seen ready for another tour of days.

One of the advantages realized, in addition to the disadvantages eliminated, is the small cost of construction and the case of maintenance and repair. Even if struck in a vital spot, the target airplane can be readily put back into commission. Again, the target airplane can be operated in a minimum of space, at a place convenient

Target plane ready for launching from its catapult. A two-cylinder engine drives the twin propellers

advantages The targets cannot be maneuvered sufficiently, and they do not simulate the outline of an airplane. The pilot of the towing airplane may be struck by a stray bullet—although such a mishap has not occurred to date. Further, the rife or machine gun personnel on the ground have no

way of telling whether their fire would have

reached a vital spot of the airplane. All these disadvantages will be cluminated, and many new advantages will be secured, by the use of a small radio-controlled airplane which is in process of test by engineers of the Army Arr Corps at Wright Field, Dayton, with Captain George

V. Holloman directing the experiments. The little airplane is only about one third the size of a normal combat sirplane at reduced speeds and has a 12-foot wing spread. It is flown at reduced speeds and has a service ceiling of about 5000 feet. The target sirplane is maneuvered solely by a radio transmitter controlled by an officer standing in a safe position on the ground. By means of a small hand-held instrument, similar to the dial of a telephone, the ground officer can cause the target plane to turn, bank, dive, or zoom, giving realistic representation of a maneuvering aircraft.

When all is in readiness for the take-off.

for any branch of the service. Previously, anti-aircraft practice could be undertaken only in the vicinity of a large airdrome.—

FOUR BLADED

PROPELLER

THERE seems to be no difficulty in increasing airplane engine power almost indefinitely. At least the power of aircraft

Fetzr blades for powerful engines

engines seems to go up a hundred horsepower or even more per annum, and such progress has been continuous for at least ten years. The increased engine powers introduce a serious difficulty, however, in the matter of the propeller.

To shorth the power of, say, a 2000 horsepower eagine, in a relatively small strylane, the diameter of the propeller becomes inconditately large. This means a long, heavy, and clumay landing gear, which is a serious disadvantage. Also, the speed of the ends of the propeller blades becomes so high as to approach the speed of sound—with consequent loss of thrust and efficiency. As a result of these facts, Curties pro-

As a result of these facts, Curties propeller engineers have now replaced the three-bladed airscrew by a four-bladed one. Tests have inducated that this new trend in propeller design is quite astifactory, though even with the four blades there is some sacrifice in efficiency compared with airscrews carrying less power for the same diameter.

The airplane shows in the photograph is the Curtiss P-SA pursuit, when his highly popular with Army Air Corps pilots. The blades of the aircrew are of thin aluminum, and are electrically controlled. The pilot can select the pitch, and then the airscrew can be used as a constant speed propoller. When the conjent stops it is possible to feather the blades fully; that is, to set them completely on edge to the astrateam. This combination of characteristic is very completely one shows the complete of the compl

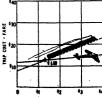

At high altitude the absorption of power of a supercharged engine is still more difficult. Some engineers even believe that in addition to pitch control, and four blades, airscrews may need a change-speed gear or even extensible diameter. In fact, one company is already working on an extensible diameter propeller—M. K.

ECONOMY OF AIR

TRAVEL

THE following figures have been submitted to us by an airline company, whose name we do not mention for obvious reasons. Even though they come from an interested source, the figures and arguments are so logical and so trustworthy as to deserve full crodence.

It is true that air travel fares were once considerably higher than those for other types of transportation. And although rates for air travel within the last few years have

TRANSLESS SMART-DOLLARS FER HOUR As the electroles's salery good up, the contemp of acrial trans-

been substantially reduced, air travel is still in many cases a higher fare form of transportation. Yet the differential between air and railway travel is not great, and practically disappears when other expenses are taken into consideration. Thus a round trip by air from Atlanta to New York costs only \$2.184 and taken only 12 hours. Meals are free and there is no thyping. This same round-rip by rail cost \$83.75 for fare alone, cound-rip by round. The taken is the contract of t

When salaries of business executives are taken into account on a conservative basis, are travel actually becomes cheaper. For a trip of 200 miles, when salaries per hour and time saved are taken into account, the business man saves money when his salary reaches the figure of only \$1.18 per hour.—4. K.

OIL CONDITIONER

UBRICATING oil in motor cars accumulates impurities such as water, acid, dust, carbon, and metal particles. The heat of the engine plus the oxygen in the air form engine-logging products generally referred to as "varnab." These resins and tars affect the engine's performance, and in some cases may "freeze" new motors Frequent cleaning of the oil by passing it

Thoroughly clean oil, free from all dirt, impurities, and acid, is delivered to the motorist from this oil conditioner. Dirty oil from the crankcase is pumped into the device, where it filters through a cartridge and is cleaned

through a new device called the Filtermaster will stop the trouble caused by such im-

The Tillermaster, wheh is made by Clean Gils Corporation, is a simple stanklite affair into which the oil is pumped from a motor-car engine. The equipment does not do an actual job of reclaiming in the ordinary sense, but does clean and wash the oil of all impurities. It uses a special, replacable filter carridge which absorbs the impurities, and a neutralizing alkali to counterent the acidity of the oil as it passes

The machine ordinarily runs an average of 25 gallons at a time, so that the car owner does not actually have returned to him the identical oil which was pumped from his

The oil conditioner

car. The theory of operation is that a garage owner would either simply swap clean oil for old or make a standing contract with steady customers to keep clean oil in their motors for a specified period at a specified

PAPER COATING FROM CORN

AVAILABLE as a by-product of corn processing. Zein, an industrial protein, gives promise of outstanding usefulness in the paper costing field. As a decorative coating for magazine covers, labels, and smilar uses, it gives a pleasing surface without the high gless of some other coating metrals. It can also be formulated with a metral of the control of the product of the control o

Commercially produced as a fine powder of slightly yellowish color, Zein contains not over 2 percent non-protein solids. The potential yield is approximately one pound per bushel of corn.

HEAVY

A CUBIC inch of matter from a recently discovered "white dwarf" star, ammed Wolf 457, would weigh 9600 tons. This is just under the weight of one of our latest Navy cruisers. A particle of this could not be supported by any known matter on earth, for it would "sink" through even our strongest metal.

INFRA-RED RAYS SPEED SEED GERMINATION

INFRA-RED rays have been successfully used to increase seed germination by as much as 50 percent. This is the report that comes from the Leray Corporation, makers of the infra-red lamp which was described in our January, 1989, issue, based upon tests made some time ago by the Sanders-Durling Entomological Service of New

York. These tests indicated a very noticeable stimulation as well as an increase in germination.

In these tests, seeds were subjected to the infra-red rays from the Leray lamp. This lamp is attached to any 110-wolt electrical circuit, and is moved slowly and carfully at a set distance above the surface of the seeds. Ten seconds has been found to be the most effective time for keeping the

lamp in any one position.

The success of these tests indicate possibilities for improving gardens by insuring better germination.

GEMS

THE Smithsonian has just had added to its collection the largest topaz crystal ever known. This crystal, totaling 350,000 carats, compared with the ordinary gem topaz of four or five carats, was found in Minus Gerase Province of Brazil.

DIKETENE AND THIODIGLYCOL

DIKETENE, to which the structure of viryl beta acetoloctone has been as signed, was described at a recent meeting of the American Chemical Society. It is a more undustral chemical which is now available in commercial quantities. Its industrial able in commercial quantities, it industrial importance hear in the valuable products which may be synthesized from it because of its excentional reactivity.

Of current interest is thiodiglycol, also discoused at the meeting. This chemical is useful chiefly as a starting material for the manufacture of mustard gas. A new method of synthesis from ethylene oxide and hydrogen sulfide was described, which is much less expensive than former methods.

UNBREAKABLE WATCH CRYSTALS MELTED INTO PLACE

UNBREAKABLE watch crystals, in use for many years, have had a disadvantage in their inability to exclude dust from the face of the watch since their flexibility

Melting an unbreakable watch crystal into place. Inset shows a crystal, mounted in position, from which part of the surplus plastic material has been trimmed

causes them to bulge and leave open cracks at the edges. A new method of mounting such crystals on watches, developed by Dutcher Bros., Inc., gives a perfect seal at the edges.

This corporation puts the watch into a machine especially devised for the purpose, places an oversized crystal on the watch, and then melts it into place under slight pressure at a temperature of 225 degrees. Fahrenheit. No cement is used, but the melting at the periphery of the crystal seads it to the rough deges of the beec? The surplus plastic material from the edge of the crystal is then trummed off.

FLUID ANALYSIS

BY LIGHT

ANALYSIS of colories fluids and some colored fluids which appear colories as a colored fluids which appear colories as colored fluids which appear colories as the colored fluids of the colored fluids. The colored fluids are colored for colored fluids fluids are colored for colored fluids. The colored fluids fluids are colored for colored from the infar red, and second for determining rapidly the concentration of colored ingredients of solutions. It is particularly valuable in industrial control or inspection laboratories, being uned, for example, to determine minute quantities of lead, copper, and other foreign aubatoance which may be in

canned foods and beverages.
The Model JO RS-photometer utilizes the
proved basic principles of spectrophotometry. A control with a linear scale, calibrated from 350 to 1000 millimicrons, from
the near ultra-violet far into inferred, permits selection of any 35-millimicron hand
been supported to the selection of the spectrum
than passes through the sample
liquid.

More or less absorption occurs, depending on the nature of the fluid being examined. The unabsorbed light is collected in a photocell and quantitatively determined to better than 0.5 percent. By substituting a standard solution in the same light path,

the ratio of the light intensity at the selected wave band is inducated directly as percent transmittance by any Model 3 Coleman. Electrometer. These results are independent of line voltage fluctuations and do not depend on colored filters. These data are precuse expressions of fundamental units of color chemistry—percent of transmittance at known wavelengths of visible or invisible light.

VARIABLE POWER

Telescopes

CHARP image in steps of five powers, are claimed for now televopes recently an ounced by Wolfersak Optical Company. No one televope great though there are as many as its ranges in some of the new televopes. Under the trade mane of Vari-Power, these televopes have harded fecusing ring; non-hosening, non-whole joints that are dust-proof; and chrome-plated rust-proof tubes.

PENCILS

NEARLY four million lead pencils and 2600 gallons of ink per year are used by the employees of the steel industry.

BELL-RINGING RADIO

DEVICE

A NEW bell-traging device, which permits emergency radio calls to be put through as easily as telephone calls, has been developed in the Forest Service Radio Laboratory at Portland, Oregon. This standby unit has heen developed for the new Type T ultra-ligh-frequency radio set, 30,000 to 40,000 kilocytek. Any Forest Service ultra-high-frequency radio set, however even the lightest eight-pound portable even the lightest eight-pound portable—

PORTABLE METAL

FIRE ESCAPE

A NEW fire escape which combines the strength of a permanent fire escape with the portability and ease of handling of a rope ladder is shown in one of our illustrations. A product of Engineering

Development Company, this unit may be anchored on any window all without difficulty, and then dropped to the ground as one would drop an ordinary rope ladder. In the 16-toot length for a two-story buildin, the ladder weighs 15 pounds, while in the three-story length—24 feet—the weight is 20 pounds. The load capacity is 1800 to 1

FIRST YEAR OF THE CIVIL AERONAUTICS AUTHORITY

I was quite appropriate that at the completion of the first year's work of the Civil Aeronautics. Authority, Charman Robert H. Hinekley should make public a statement as to its own activities and those of civil avaition as a whole, which, from every point of view, have been highly astis-

In June, 164,578 passengers were carried, or 64 percent more than in the corresponding month of 1938. During the first six months of 1939, 1627 sirplanes were produced, while in the same period for 1938

Business begins with BUYING

by Westinghouse

- A manufacturer must buy before he can sell. He must buy the raw suff that goes to make the finished product; he must buy machinery and the plants to house it, and must hire the men without whom the finest equipment in the world would be just so much worthless scrap.
- In our particular case, being a large manufacturer, we are first of all an enormous byer. If all of the copper wire we buy in a single good year were converted into sixteenthich wire, the strand would stretch over 209,000 miles—enough to wind eight times around the Earth. And the insulating yarn we buy could be looped 36 times from Earth to Moon.
- We use enough steel and iron each good year to build two railroad tracks 2,290 miles long—or a couple of Oakland Bay Bridges.
- We buy a lot of gas, oil, hydrogen, nitrogen and oxygen; we are a huge consumer of gold, silver, mercury and tungsten. You won't find the kind of sapphires we use for bearings in a jewelry store—nor would you find a jewelry store in the world that could supply the 20,000,000 jewels we need each year. We even buy diamonds and use them as dies for drawing very fine wire. Though most of our pur-fine wire. Though most of our pur-

- chases run into tremendous quantities, one of them, last year, amounted to just one ten-thousandths of a gram. That was radium, and it cost \$300.
- Every one of the forty-eight states and Alaska are important suppliers of ours. Twenty foreign countries contribute materials not produced in America. Almost literally, every industry and every farm produces something that we use.
- · "What in the world can a farm grow for Westinghouse?", you ask. Just to name a few things - oat hulls, molasses, grain and sugar cane for alcohol, dextrine from corn, flour and straw for making foundry cores, lard, sugar, lumber and tapioca; also leather, wool, cotton and meat products. It all adds up to this. Each vearwebuymorethan\$100.000.000 worth of the products of industry and farmers. Some of our people have estimated that these purchases give work to about 36,000 persons annually. This is in addition to our own 43,000 employees who fabricate these materials into a vast number of machines and appliances which increase the permanent wealth of America.
- Who gets this wealth? Why, the industries and farmers who sold the materials to us, of course. It's really nothing but an elaborate process of swapping. We swap what we make for the materials needed to make our products.
- That's why we cannot consider ourselves as a separate industry. Along with thousands of others, we are merely an essential cog in the tremendous process which has created American prosperity and the American way of living.

QUANTITIES LIMITED-ACT QUICKLY

For sale by SCIENTIFIC AMERICAN, 24 West 40th Street, New York, N. Y.

only 850 civil aircraft were constructed. Today 25,144 pilots hold certificates, or 5000 more than a year ago. There are 11,160 certificated airplanes or 1400 more than a year ago. Even without the C.A.A. pilot training there should be 36,000 certificated pilots by the end of 1940, and 43,000 by the end of 1941.

Federal airways have been increased to a total of 25,000 miles, with improvements in aids to navigation more than keeping

The C.A.A. flight training program will give us 10,000 student pilots next year.

The Washington airport at Gravelly

The Washington airport at Graveny Point is beginning to take shape, with work proceeding rapidly under the supervision of the Corps of Engineers of the United States Army.

The existing system of scheduled airmail carriers is now legally a public utility. Certificates have been issued which make the existing airlines secure in their positions and free to plan for further progress.

The safety record of the airlines has been

remarkably good. They flew 72,900,000 miles per pilot fatality; 51,700,000 passenger miles per passenger fatality; and 24,300,000 miles per fatal accident. These records are nearly three times better than the same records for the year 1938.

Technical developments have been equally satisfactory. Ultra-high frequency radio ranges operating at 63 and 125 megacycles at Indianapolis and Pittsburgh have been proved to be free of static whether from natural or artificial causes. This freedom from static, particularly in bad weather, is one of the most important elements in air transport radio communication and safety. Contracts have been let for three units of a new and approved type of ground direction finder. The blind landing system nearing completion at Indianapolis is one of the most comprehensive yet devised

The Safety Board has developed its meth ods of accident investigation, with hearings conducted at or near the scene of the acci-dent within a remarkably short time there-after. The publication of reports after such investigations has given aircraft constructors and operators much valuable in-formation.—A. K.

CHEAPER COPPER

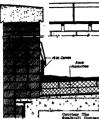

PROTECTION ON

FIRER BASE

OPPER has been valued as a protective metal in building construction for many centuries. However, its high cost milimany centuries, however, its high cost min-tates against its use in many places where it would do a superior job of protecting against leakage or dampness. At least two companies—The Sisalkraft Company and the Angier Corporation-have provided an inexpensive product for use in all types of flashings, which combines the protective value of a very thin copper sheet with the strength and body of an adherent impregnated fiber.

Both of these companies use very thin sheets of pure copper completely free from pin holes, produced by electrical deposition of the copper on lead drums.

In the case of the Sisalkraft product, this thin sheet is bonded under heat and pressure to their own tough product called Sisalkraft The resulting sheet, which may be made in different thicknesses for different spatialla-

How thin sheet copper, bonded to a fiber base, is used to waterproof a parapet and damp-proof the insulation under built-up roofs

tions, is flexible, will not kink or crack, can be cut to fit with ordinary shears, and is easily bent to place by hand.

The Angier Corporation's product, called

The Angier Corporation's product, called Copperakin, is backed up with tough and durable paper to provide the advantages of regular 16-ounce copper at approximately one fifth the cost. The backing material is called Brownskin, is resilient, and can stretch or shrink with the expansion and contraction of the copper due to temperature changes.

FROZEN SOLAR ENERGY

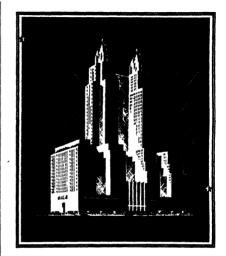

PLORIDA sunshine shed its glow at the New York World's Fair one day, playing a rôle in ceremonies at the Florida State Exhibit Building. Flown from Jacksonville

a rôle in ceremonies at the Florida State Exhibit Building. Flown from Jacksonville in nert form, the sunshine had been absorbed by luminescent powder and "canned" by being frozen in liquid air.

The feat of rendering solar energy inert, then transporting it nearly 1000 miles and releasing it, is believed to have been accom-

Mr. Hibben measuring a quantity of powder self-in as was used for demonstrating "canned" sunlight

THERE IS ONLY ONE "WALDORF"

Its towers, sharply etched against the sky, are modern as tomorrow...yet its tradition of hospitality goes back to a grand and spacious age.

Its glamorous restaurants, favorite gathering-places of metropolitan society, are vibrant with music and gaiety . . . while above, its rooms are star-quiet in the night, peaceful as the hills of home.

Its guests include the great ones of a busy world ... and the quiet, unassuming people who make that world go 'round.

Experimenters - Schools - Field Workers

An Accurate Balance at a Price Within the Reach of All

Sensitive to 2/50 gram Weighs up to 100 grams Compact-No loose parts Modern, durable construction Small convenient size Handsome streamline design

Now permissible for auxiliary use in drug stores (N. Y. C. Serial B17.)

Never before a balance with all these exceptional features!

Fixest Quality—Made of tested materials Its construction will appeal to laboratories desiring the best equipment. The Backelite cup is unaffected by practically any substance that can come in contact with it: the tool steel knife edge and agate bearing will give long life and securacy.

Extreme Sensitivity—Weighs to one decimal point farther than the usual low-priced counter scales and serves nearly every laboratory purpose abort of precise analysis. The capacity of 100 grams is ample for the delicate

weighings made in the usual course of teaching, organic synthesis, experimental work, compounding, photographic work, etc. Compact-Convenient—Does not monopolize a laboratory table Placed on the desk of the busy technical executive, it will soon become

Its small size makes it possible to carry it on inspection and testing trips at a distance from the laboratory. It is small enough to be carried under the arm or in an overcoat.

Graduated in either the Metric System (grams) or the Apotheonry's System (grains, drams and susces), in ordering, please indicate which of these you desire.

De Luxe Library **Editions** of SCIENTIFIC AMERICAN

Make them yourself; protect and preserve your copies with a PERMO LIFETIME BINDER

It holds a year's issues

SO MANY readers preserve their copies year after year and have asked for binders that, after thorough investigation of binders, the editors of Scientific American found a type that is most saintactory, considering cost, ease of handling, and durability. It holds a full year's issues (12), has an efficient patented lock; is atrong and durable; and it covered with a rich, pebbled, rid leatherethe besuitfully samped in gold. Magazinis are bound in with a map and are held positively in place; no punching necessary. In ordering, state what year (1985, 1939, e.e.) is to be tamped in gold on the backbone.

Each \$1.50 postpaid in continental U.S. (\$2.00 postpaid elsewhere)

SCIENTIFIC AMERICAN, 24 West 40th Street, New York

plished successfully for the first time. Is was directed by Samuel G. Hibben, lighting engineer for the the Lamp Division of the

Company.

In absorbing light energy, scientists believe, the luminescent powder actually undergoes a temporary change in physical structure. The theory is that the outermost orbits of electrons, which make up the molecules and stoms of the powder, are distorted or literally moved from one energy level to another when excited by impinging light, actually imprisoning some of the light.

Then, just as a piece of sponge rubber springs back to its original shape on being released from the hand, so do the electrons tend to return to their normal positions, and in so doing, give out the light energy they have imprisoned.

ELECTROMETRIC pH STANDARDS

MIME-SAVING capsules of chemicals in powder form are now available for use as reference standards for checking electrometric pH apparatus. The "Hydrion" Buffer Standards, as they are called, when dissolved in the proper amount of distilled water, maké solutions, the pH of which have been electrometrically checked by the manufacturer Five different standards are offered, ranging from 3.0 to 9.2 in pH value.

STORYTONE

AN electrical musical instrument that cap-tures all the richness of tone, volume, and color of the grand piano and is housed in a cabinet no larger than a spinet, has been developed by RCA engineers in collaboration with craftsmen of the Story & Clark Piano Company The new instrument will be marketed through Story & Clark dealers under the name Storytone "Voiced by RCA Victor."

Providing the music of the piano, the radio, and the phonograph, the Storytone utilizes specially designed electrical amplifying and speaker equipment to reproduce the full range of tones with sparkling clarity and brilliance. The volume is easily controlled by a single knob located at the end of the keyboard panel. The range is so flexible that a single turn of the knob produces the softest whisper of a note or brings forth the full tonal blend of a powerful crescendo

When the volume control is adjusted to conventional piano range, the Storytone rivals the largest concert grand piano, and when the amplifier is turned low or comwhen the ampliner is turned low or com-pletely off, a pleasing harpsichord effect is produced. In addition to the customary "damper" and "soft" pedals, the instrument is equipped with a "swell" foot pedal with which organ effects may be produced through regulation of the amplifier volume.

, Bench of the Storytone, opened

Used in conjunction with either a radio or phonograph, the Storytone reproduces radio programs or recorded music. A special piano ench has been designed which contains a bench has been designed which contains a radio and phonograph located separately in two sliding drawers placed directly beneath the seat. A simple plug-in connection per-

mits easy operation of either instrument. The Storytone may also be played while the radie or phonograph are in operation. Unaffected by either temperature or hu-

midity changes, the instrument's tone is developed electrically through a seven-tube amplater of 20 watts output. Set in motion by mechanical vibrations of the strings induce corresponding electrical vibrations in the coils of magnetic pickups. These electrical vibrations are then amplified by radio tubes and converted into audible musical tones by a powerful high-fidelity loudspeaker.

JUNIOR ARC WELDER

FOR garages, blacksmiths, construction engineers, machine shops, and others, a new 200 ampere arc-welding unit, either belted or direct-driven, has been developed by the Lancoln Electric Company A compact unit, with its own control board, this welding unit weighs approximately 320 nounde

OLD BUILDINGS MADE FIRE RESISTANT

FOUR out of every five deaths caused by tenement house fires—that annually cities-can be prevented.

A four-year campaign by the New York building department to make Old Law tenements more fire-safe, has succeeded in re-ducing the number of deaths resulting from general conflagration in them from 38 in 1934 to 7 in 1938.

The campaign, backed by State legisla-Law "tinder box" into a more fire resistive building by requiring that it be equipped with a fire-resistant cellar ceiling, fire larded stairwells, and modern stair-type fire

The total cost of all three improve according to general estimates, is about \$50 a family—inexpensive and permanent life insurance for the families protected. Fire-retarded stair halls, the basis of the

new fire protection, is a comparatively new contribution to building safety. It is an attempt to make the ordinary wood stud and plaster stair-hall walls of the average

tenement house more fire-resistant so that they can confine the fire to its place of origin instead of serving as a giant fine for the dames from first finer to rorof. Various methods of fire-restarding are today approved by the New York Building Department. The simplest method, howere, is one which requires no changed or estimate construction. Widely used in New York City, it employs granulated min-stream of the confiner of t heat-stopping properties that has been used

near-scopping properties that has been used for many years to insulate the roofs and side walls of building against heat and cold This same material is easily adapted to stair hall fire-retarding. Small holes are cut into the existing plaster and the mineral wool is then pumped into the hollow partiwood is their jumped into the hollow parti-tion to a pressure of ten pounds per square inch. The result, which complies with Department standards, is a five and a half inch wall with a thick inner fireproof core By effectively withstanding a temperature of 1700 degrees, Fahrenheit, for one hour. such a wall prevents the spread of the fire and permits the safe evacuation of the

STEEL

DURING 1939, the research program of the steel industry contemplates a total expenditure of approximately \$10,000,000. This is 15 percent more than the total of \$8,700,000 which was spent for the same purpose in 1929.

120,000 PICTURES PER SECOND

WHAT is believed to be the fastest camera in the world, shooting 120,000 pictures per second, does not employ glass lenses. Instead, it has 1000 holes .01 of an inch in diameter, or approximately the size of a pin hole. The drum-like camera is used in the study of electrical arcs so that en-gineers may analyze the behavior of such arcs in circuit breakers and other electrical

apparatus.

The cylinder is 14 inches in diameter and is driven by a ½-horsepower motor which speeds up to 7200 revolutions per minute. At such a speed, each of the 1000 pin-hole

The pin-hole drum, carrying film of the high-speed camera, revolves behind opening at right center

openings is open for only 1/120,000 of a second. The size of each of the 1000 pictures taken by the camera, with a single film, is nine millimeters square, or about one third

of an inch on a side. While intended primarily for the study of electric arcs, other applications for this camera may be found.

THE CHEMICAL STRUCTURE OF VITAMIN K

HEMISTS working independently at two different institutions, Harvard University and Saint Louis University, have determined the structure of vitamin K, the blood-clotting principle. The structural formula, according to the chemists, is 2-methyl-3-phytyl-1, 4-naphthoquinone.

The synthetic vitamin was checked by comparing spectra, color reactions, anti-hemorrhagic activity, and chemical prop-erties, with those of the natural vitamin obtained from alfalfa.

The synthesis is declared to be an effi-cient and practical one suitable for manufacturing purposes, and the pure vitamin is thus made available for use in medicine to prevent and control hemorrhages.

VERSATILE DEHYDRATOR

THE Henry Cartridge Dehydrator, originally designed for air conditioning and refrigeration, is finding increasing use where need exists for removal of moisture from chemicals in solution, and in air drying.

The major features of this Henry dryer are its patented dispersion tube and re-placeable dehydrant cartridge. The per-forated dispersion tube—exposing the en-tire volume of dehydrant to penetration by the fluid or air—extends along the central axis of the dehydrant column. This construction is claimed to reduce the pressure drop, prevent channeling and resultant loss of efficiency so often found in dryers of conventional design.

Refill cartridges make recharging of these Henry dryers exceptionally simple and easy. Cartridges are available charged with acti-

SCIENTIFIC AMERICAN

"FLOATING" BRAKE

LINING

SINGLE piece of "floating" lining is a novel feature of a new design brake adopted for the recently-announced Crosley This bining is not riveted, but "floats" freely between the brake shoes and the drum, thus affording braking action on both its surfaces instead of only one side as

The lining "floats"

in conventional brakes. An interesting feature of this brake is the "creeping" or slowly rotating action of the lining, which distributes wear evenly over the entire lining surface, thereby greatly increasing its serv-

ice life. Should it be necessary to replace the lining after prolonged service, it is necessary only to remove the wheel, withdraw old lining by hand, and merely slip a new length

of lining in place. The brake shoes, which provide about 350 degrees of contact with the inner lining surface, are made of a special nickel-chrome iron sufficiently flexible to conform exactly with the drum contour when braking pressure is applied

FALLING DIAMONDS

DIAMONDS actually fall from the sky. That real diamonds exist in meteorites has just been demonstrated for the first time by X-ray examination of hard, black crystals in a specimen from the celebrated Meteor Crater in Arizona.

The present specimen was obtained not long ago by the Smithsonian Institution, and some of the suspected diamond inclusions were ground out. They were turned over to mineralogists of the Geophysical Laboratory of the Carnegie Institution of Washington for study by the most refined methods, with the result that the true nature of the inclusions no longer is in doubt.

The conditions under which meteorites bably were formed would be favorable for the formation of diamonds, provided the requisite carbon was there in the first place.

Demonstration that the inclusions actually are diamonds recalls the futile efforts made to drill into Meteor Crater in the hope that a big diamond mass would be encountered. After drilling straight downward for about 1200 feet the drills struck a resistant

Marlin Razor Blades

Old Company Slashes Selling Costs-Offers 40 First Quality Blades for Half a Dollar

The Marlin Firearms Company, famous for the manufacture of fine guns since 1870, has found a way to bring the finest quality razor blades to shavers at a fraction of their usual cost.

Basic patents having expired, Marlin Basic patents having expired, Marlin pays no royaltics. And by selling in "wholesale" quantities, with economies in packaging, shipping, etc., the company effects savings which are passed on to the consumer

Made of the finest Swedish surgical steel, for standard holders, Marlin blades are offered at the unprecedented price of 80 for one dollar, 40 for fifty cents, Under the company's ironclad guarantee, you can try these new blades without risk. Use five, and if you do not find then equal to the best, you may return the balance and get your money back.

Mail the coupon today for a "wholesale" package of these fine blades! Marin will nay the postage.

material through which they could not per trate. Efforts to sink a shaft were defeated by striking water. Geophysical experiments indicated a very heavy mass in the neighborhood. None of this, of course, would be accepted by geologists as positive evidence of the existence of a large diamond mass. There is even some question as to whether the "shooting star" responsible for forming the Meteor Crater actually penetrated the earth at all. It may simply have exploded and its fragments scattered over the neighborhood where many of them have been

picked up in the past century.

The diamonds found in the Smithsonian Institution specimen are not of gem quality. They are very good black diamonds—even more valuable than medium-rate gems because of their use in industry.

SWEETS FOR HIGH.

FLYING BOMBERS SWEET emergency rations may be carried by pilots of bombing planes cruising at 11,000 to 20,000 feet altitude and peering at the darkness of a blacked-out city, to counteract difficulty in reading their brightly lighted instruments. This may be concluded from experiments reported by Dr. Ross A. McFarland.

Adaptation of the eye to dark and light is seriously affected by lowered oxygen pressure, Dr. McFarland and Dr. W. H Forbes found at Harvard University, but the effect can be counteracted by a dose of glucose. The eye fails to adapt normally because the amount of oxygen in the nervous tissue is decreased. The trouble is in the nerve elements of the retina and central nervous system, not with the photo-sensitive substances in the eye .- Science Service.

Poison Gas

HERE are the most important known polson gases which have been found effective in warfare. Many of them were developed and used during the World War. Possibly others, in addition, will be used

during the present war in Europe.

Mustard Gas. Chemically, dichle sulfide. In pure state almost ederless. In World War smelled like superand or sarlie.

Inc. It is used for testing plaster, brick, or concrete surfaces before decorating them, or for tracing leaks. It gives instantaneous readings of "dry," "wet," or "very wet."

This device is a simple electrical meter with an extension cord on the end of which is a handle containing two projecting needles. These needles are punched into the surface being tested, thus completing an electrical circuit. The flow of current between the needles and through the wall at that point will thus register on the dial of the meter without any calculations, the amount of current flowing being dependent upon the moisture of the wall. The circuit used is said to insure the highest possible accuracy regardless of whether the enclosed battery is new or old. The dial may be

ADOLE TO TO TOP SOPRIOR OF ADOLE OF ADOLE OF THE ADOLE OF

THE PROBLEM OF THE WEIGHTS

ONTINUING our series of mathema ical brain-teasers, we offer the Prob lem of the Weights. It is, according to the author, a paraphrase of one which is over 300 years old, and one of the few really good problems in arithmetic. The answers and the solution will be given next month Meanwhile any correspondence concerning this or previous problems should be addressed to Lieutenant Commander Leonard Kaplan in care of Scientific American, 24 West 40th St., New York, N. Y. All letters will be forwarded unopened.

It is desired to obtain a set of eight weights for a beam balance such as is shown in the accompanying sketch. They are to be

used for weighing to the nearest ounce any object up to, and including, 205 pounds. Each may be used on the left scale pan, or on the right, or not at all. The problem consists of three parts as follows:

I) Determine the magnitude of each weight. II) Prove that eight is the least number,

and, that

III) These eight weights have the least total weight of any set which will fulfill the conditions of the problem.

Heavy, oily liquid of dark straw color. Evaporates slowly at ordinary temperatures; Evaporates slowly at ordinary temperatures; thus is a persistent type of gas. Frequently diluted with another poison, chloropicrin, to keep it liquid in colder weather. Has a delayed action on body. First symptoms, stching and blistering. Especially damaging to eve's cornes. In eve, tissue degeneration begins two minutes after exposure to dilute concentrations. If gas is swallowed, symptoms of nauses, vomiting, and diarrhea develop. Gas very penetrating. Goes through ordinary clothing, rubber, and even leather. Is 50 times more toxic than chlorine.

Chlorine Gas. First gas used in World War. Two and a half times the weight of air. Clings to ground. Fills shell holes, de-pressions, and dugouts. Greatest action occurs in presence of moisture. Major action is on respiratory tract with symptoms of

choking, coughing, and suffocation.

Phosgene Gas. A combination of carbon monoxide and chlorine. Resembling chlor-ine in action but has a more delayed effect. Is 10 times more toxic than chlorine. First

Is '10 times mere porte than chlorine. First wymptons very minor, Its effectiveness mainly due to initial innocessus obaracter. Its meanes is revealed only after considerable gassing has occurred. Leustite. Chemically, chloro-viryl-dichloro-arpina. Developed secretly during World War for Gar, W. Lee Lewis of U. S. Chemicall Warfare Service. War ended just before, yas entered combat use. Has all blistinging properties of mustard gas but

more effective because it has ability to penetrate the skin. Three drops, placed on rat's abdomen, causes death in two to three hours. Is powerful respiratory irritant. Produces violent sneezing. Another variety, beta-beta-prime-chloro-vinyl-dichloro-arsine, has less blistering effect but its irritation on respiratory system is much more severe.

Toxic smokes. Chemically, diphenyl-chloro-arsine and diphenyl-cyano-arsine. Popularly called sneezing gas. Are really finely divided dusts. Can pass through or-dinary gas masks unless special filter at-tachments are provided. Effective in concentrations of one part in 10,000,000 of air. In higher concentrations, cause vomiting. Considered as poisonous as phosgene in

equal concentrations. Crying Gases. Twenty-three different varieties used in World War. All intended to produce temporary disability and con-fusion. Favorite German lachrymatory gas was xylyl bromide. Among the Allies, chloropicrin was widely used.—Science Service.

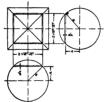

SOLUTION TO THE

PROBLEM OF THE

INTERSECTING CYLINDERS

THE problem offered last month was to find the volume of the material removed from a two-inch cylinder by a two-inch drill. The axis of the drill was perpendicular to and intersected the axis of the cylinder.

Here, as was promised, is the solution The illustration shows the section removed

from the cylinder. The radius of the cylinder is equal to the radius of the hole and has been designated as a.

Taking sections in the manner indicated, the volume, V, will be given by the expres-

$$2\int_{0}^{a} (2\sqrt{a^{2}-r^{2}})^{2} dr$$

$$8\int_{0}^{a} (a^{2}-r^{2}) dr$$

which integrates into

 $\begin{array}{l}
\dot{8} \left[a^2 r - \frac{r^2}{3} \right]_0^a \\
8 \left(a^3 - \frac{q^4}{3} \right)
\end{array}$

$$V = \frac{16}{3} a^3$$

And so for the specific value, a=1 inch, given in the problem, the volume of material removed is 5 1/3 cubic inches.

"Most readable -enswers both the personal and the astronomical questions."

YOUR FIREARMS

Conducted By A. D. RATHBONE, IV

INTEREST IN FIREARMS is traditional with American men; science has so developed them that millions yearly find sport and recreation in their use. Hence this monthly department presenting a wide variety of discussion regarding firearms, their handling, and their accessories. Suggestions from readers will be heartly welcomed.—The Editor.

Introductions Are

IN ORDER

THE brotherhood of nimreds, gun fanciers, and gun hobblyist is one fra-ternity which particularly and readily lends tailed to new and lasting firendships. This introduction of "Your Firearms" to Stending American readers is performed, therefore, with the pleasurable anticipation of cagaging with kindred souls in monthly round-table discussions and arguments in an informal, pre-sendic firend of fashion. The properties of th

It's a vast and controversial subject, this matter of guns and ammunition, and there may be times when you heartily disagree with what we have to say. By the same token there will be other instances when you are in accord with the thoughts expressed. but in any event, it is your department, conducted for your pleasure and your information. Ranging through the fields of shotguns, rifles, handguns, their applications, ammunitions, and all their various affiliated gadgets, we plan to present unusual and informative angles, current news, and timely data on new developments. Our mail box is of generous proportions- we sincerely trust you will test its capacity to the fullest avtent

BIRD SEASON SHOTGUNS

WHEN the old-time angler selects a new trust rod, he doesn't whip it as a David Harum might lay his buggy lash onto the old mare's flanks. He picks it up with the same delicate reverence that a sweler imparts to the presentation of a beautifully made watch. He tests the rod's balance; the tip waves gently as, with an easy wrat motion, he gets the general "feel." Your experienced bird shotter handles a prospective shottym purchase in much the same manner. It's the "feel" of the weapon which tells him what he wants to know

tells him what he wants to show.

Incorporated in that "feel," however, are several factors, tabulation of which, to the veteran gunner, are more or less subconscious. The weight, balance, putch, fit of stock, drop at comb and at heel are all integers which collectively contribute to an instantaneous reaction during the first moment or two with a new gun. The aforesaid veteran is entirely conversant with these component items, but he doesn't delive specifically into them until after he has applied his first automatic testing formula of 'teel,"

Should the reaction be negative, even in the least degree, the piece is either laid aside in favor of another, or the purchaser hefts the gun, tries it rather questioningly to his shoulder again, as if that shadow of doubt which first crossed his mind might have been an error. The chances are, though, that if the gun "feels" wrong, he can't be persuaded to try it, and if he does, the resultant lack of complete confidence will affect his shooting.

All this applies to the man who knows his guns How then, to answer the novice, the new chap, who asks: "Which shotgun should I buy?" The logical answer to that one 18, of course, another question: "What

The author sheld

game do you want to shoot?" But this deasn't give the neophyte much satisfaction. However, we can say that stock fit, portability, tragger pull, gage, gun balance, lines, and certain minor mechanical details are primary features to be considered in selecing a field gun. Let the novice forget momentarily the more technical angle.

Regardless of weight, gage, balance, or bore the gun must fit the gunner or the results will be disappointing. A heautiful and expensive field piece may be utterly useless if the stock is either too short or too long. The best we can say is to find a gun which feel "sight" then it comes up to the regardless of the stock of the stock of the properly fitted new sait of clothes—and stay with it long enough to give it an adequate trial. If, then, you can't hit what you aim at, take it back for a check-up of all phases. We have listed portability, or weight, as the second item for consideration because it is the exceptional city dweller today who can walk three or four miles without feeling tired. In our estimation field guns should range between 6½ pounds and 7 nounds 6 ounces when empty, and while that may not seem like much gun to carry, there are also shells, frequently heavy cloth-ing and, it is to be hoped, some game.

Trigger pull in your shotgun is as ımportant as acceleration in your motor car. Both are vital factors in performance and safety, and, just as acceleration in automobiles is not always satisfactory, so in many shotguns the trigger pull will not be perfect. A 4 to 5½ pound trigger pull on a double barrel, 12-gage gun weighing around seven pounds will be found to be pretty close to correct, and although lighter pulls in lighter pieces may be smoother, too much reduction in the pressure brings in the problem of accidental discharge.

As to gages, it is quite universally agreed that the 12, 16, and 20 are the popular sizes in field guns throughout the country. To attempt to designate whether that new gun should be an automatic, a pump, a double barrel, or one of the over-and-unders would be rather like trying to tell the trout fisherman which fly to use. We do feel, though, that if you've been used to rifle shooting, you will find the single sighting plane-that is, the pump, the automatic, or the over-and-under-better suited to you.

Regardless of which gun is eventually chosen, remember, it is like your golf clubs, your tenns rackets, your front or bass rods. All require constant use and practice to get the most out of them, and that, we might observe in closing, is one reason why we have so many skeet fields.

Pot-Shots

AT THINGS NEW

WINCHESTER AND WESTERN SUPER TRAP AND SKEET LOAD now available in standard shells featuring a new crimp. In this de-parture from the time-worn method of placing a card wad over the shot, these com panies have joined Remington, who an-nounced their new crimped shell last spring.

Using two cameras taking instantaneous ultra-high speed exposures, the two accompanying pictures by flash photography show how the shot charge from the same crimpedshell load is propelled targetward—from right to left. The upper photograph looks down at the charge from an angle of 45 degrees, while the lower photograph looks up at the same angle. Use of the crimp has eliminated the top wad, conspicuous by its absence in the illustrations, and with no such source of interference to expand or scatter the charge, there can be no so-called "doughnut" patterns. Attention is called to the Seal-Tite wad, which has served as a piston, and which is seen dropping away from the charge.

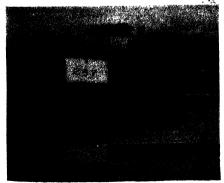

Averages taken from 100 fired 30-inch patterns at 35, 40, and 50 yards showed ow the spread of the original dense pattern center is controlled, resulting in remarkable uniformity of the number of pellets in the outer six-inch ring of the 30-inch targets. The averages were as follows:

Inner 18-inch ring Outer 6-inch ring At 35 yards 218 pellets At 40 yards 172 pellets 160 pellets 159 pellets 157 pellets At 50 yards 137 pellets

COMBINATION .410 AND .22 is Marlin's latest gun in the over-and under design. The top barrel takes .22 short, long, and long rifle cartridges and features the famous Ballard rifling. The bottom barrel is for .410 bore 3-inch shells and is full choke, with specifications similar to the .410 over-and-under

shotgun. The Marlin factory will also fur nish on order 378 Bee or .22 Hornet barrels in combination with the .410 bore and either of these can also be fitted with an extra set of .410 bore, 26-inch barrels

Start of a "doughnutless" pattern

Tricks by

REFLECTION

P ROM the simple reflection in a mirror or hody of water, to the many and varieties in which an object in prefected by particular the simple of the simple of the prefected by by reflection have been a popular pastime for a long time. Their popularity never pales because of the great variety of effects that may be obtained. There is no great photographic problem to surmount, but there are frequent instances in the work of these are frequent instances in the work of appreciation of reflection photography would have improved the result.

At the moment, we can think of five principal things that should be taken into account in producing good reflection pictures. These are as follows:

Figure 1

1. The light used should illuminate the subject and be shielded from the reflecting surface itself as much as possible, for wherever the light strikes the surface the subject reflection is restally as the surface the

wherever the light strikes the surface the subject reflection is partially or totally lost. 2. In focusing for the reflected image, the focal point is not the loss on of the rethe focal point is not the loss of the rethe position of the subject to the reflecting surface. However, this will obtain only from the point of view of the subject. That is, it would be true if the camers were placed alongaide the subject or at some point to the left or right of the subject, on a plane with the latter, equally distant from the reflecting surface. Since this is not always the case, the more practical way to put it is to say that the point of focus is the distance from the subject to the reflecting surface plane the distance from the surface

Figure 2

3. The angle of the camera should be such as to make the most of the reflection, which is the chief reason for the picture. This may sound like unnecessary advice because ceemingly so obvious but a glance at some reflection picture efforts will show how frequently these pictures show the reflection in a position of minor emphasis.

A Adequate expoure for the reflection, depending on the reflecting capacity of the particular surface used, is another point to watch. An exposure that will be correct for the subject itself under a given intensity of light will not always be right for the reflection. A mirror or calm body of water will give of the brightest reflections, pre-

Figure 3

Figure 4

tically equal to that of the subject direct. A less efficient reflector may take twice as

much exposure or more.

5. What cannot be accomplished com pletely by point 3 in the matter of properly composing the reflection picture should be done in the printing or enlarging through "framing" or masking. More than is desired may be included in the picture because of

may be included in the picture because or the focal length of the lens or because of an enforced distance from the subject. Figure 1 litherstees a straight reflection in water puddles, plus the subject itself, while Figure 2 might be termed a cort of trick effect in an ordinarily straight reflection or the subject is an endinary straight reflection. urical educat in an ordinarily straight reliecting surface— mirror. A ceiling comprising a number of separate mirrors joined together "hereka" and duplicates subjects wherever the latter appear at the mirror joines. The stiple "straw"-like units are tubular lengths.

is an ordinary window will serve as

a reflecting surface almost as efficient as a mirror. Witness Figure 3, in which a desk and chair, even the door of the room, are faithfully reflected in the window, through which also may be seen the lighted windows in buildings in the distance. Inclusion of the window helps to clarify the picture.

A curious trick effect is shown in Figure 4, which was photographed through a window facing the street at the other end of an empty store. The late afternoon sun coming from the direction of the window shown in the picture illuminated the buildings reflected in the left third of the picture.

Figure 5 is an example of distortion by reflection and foreshortening, or close view-point. The reflecting medium is an alumi-num surfaced coffee pot. The odd vertical reflection is the face of the subject, which was reflected upright from the convex part of the pot and inverted from the concave upper portion.

DOUBLE-DUTY FILTERS

PERSONS who own both a Contax and a Super Ikonta B are advised that a threaded adapter ring is available for the latter camera which will take the same filters as those used on the Contax, as well as the lens shade. Thus, the filters purchased for the Contax will serve for the other camera as well, eliminating the neessity of purchasing a separate set of filters for each of the two cameras.

GROUND LEVEL VIEWPOINT

ONE of the most frequently heard taboos is the one that advises never to have the camera face the subject head-on because such a pose is bound to lack interest. How-ever, like other rules and regulations meted out to photographic workers, this one may sometimes he broken with impunity. Here

You Can Win one of

PRIZES

VERYONE who owns a came E has a chance of winning a val-uable prize. Plan now to enter your prints in this contest. You may enter not more than two prints may be en tered by one contestant in any one of

Specific rules for this contest are pub-lished below. Be sure to read them before you submit prints.

RULES of the Contest

- 1. The groups will be judged independently on the basis of pictorial appeal and technical excellence. The decision of the judges will be final. In case of a tie for any prize, duplicate prizes will be awarded to the tying contestants.
- 2. Prints must not be smaller than 5 by 7 or larger than 11 by 14 Prints need not be mounted, but may be at the contestant's option
- Photographs must be packed properly to protect them during transportation
- 4. Non-winning entries will be returned only if sufficient postage is included when the prints are submitted.
- 5. Each entry must have the following data written on the back of the print or mount. Name and address of contestant, type of camera and film, enlarger and paper used
- 6 Contestants may submit no more than two prints in each group, but may enter any or all groups.
- 7. Prints must be in black and white Color photographs are not eligible
- 8. Prize-winning photographs will become the property of Scientific American, to be used in any manner at the discretion of the publisher
- e 9 Scientific American - scientific American reserves the right to purchase, at regular rates, any non-winning entry
- 10 No entries will be considered from
- e ii All entries in this contest must be in the hands of the judges by December 1, 1939 Results will be announced in our lasue dated February 1940
- 12 This contest is open to all amateur photographers who are not in the employ of Scientific American.

This Contest Closes Dec. 1, 1939-All Entries Must Then Be in Hands of Judges

Address All Entries to PHOTOGRAPHY CONTEST EDITOR SCIENTIFIC AMERICAN

Over \$1300 in AWARDS

Fourth Annual SCIENTIFIC AMERICAN AMATEUR PHOTOGRAPHY CONTEST ---

Prizes for BEST PHOTOGRAPHS in EACH DIVISION follow:

First Prize

Third Prize

One \$250 "Lifetime" LONGINES Watch*

One FEDERAL No. 636 Variable **Projection Printer** (List price \$29.50)

Second Prize

One \$125 LUNCINES Watch*

Courth Drive One FEDERAL No. 128 Enlarger (List price \$17.95)

Five Honorable Mention Awards, each consisting of a one-year subscription to Scientific American

Remember that these prises are to be given in each division—or a total of six watches and six enlargers plus 18 subscriptions to Scientific American, totaling \$1.327.35 in value

First Prise watches are standard men's pocket models.
 Second Prise winners may choose pocket style or gentleman's or lady's wrist watch.

Submit Pictures in ANY or ALL Three Divisions:

Division 1. Human—including portraits and other camera studies of psonis-

Division 2. Landscapes—including all scenic views, close-ups of parts of landscapes, sesscapes, and so on Division 3. Action—including all types of photography

In each division there will be prices of two Longines watches—"The World's Most Konored Watch"—and two Pederal Enlargers as well as five Honorable Mention

THE JUDGES: McClelland Barclay, artist Ivan Dmitri, artist and photograp Robert Yarnali Richle, commercial photograp is one that we believe does so successfully. Taken on the beach in mid-afternoon, the cameraman crouched on his tummy to face the subject eye to eye and shot away just as a fortuitous breeze waved the towel revealingly out of the way. The arrangement of the towel around the subject's head, the

From ground level

revelation of only one shoulder, the highlight on one side of the face, the waving hair, the pose of the subject's left hand and the curious smile, each lends its bit towards the whole. Unfortunately, the right hand, holding the lighted cigarette, is out of focus owing to too near a camera viewpoint and the wide diaphragm opening necessitated by the fact that the subject was in shadow.

PRIZE CHANGE

DUE to war-time conditions in Europe, and uncertainty as to shipping schedules, we are forced to make a change in the First Prizes offered in our Fourth Annual Photography Contest. As originally an-nounced, First Prize Winners would make their own selections of watch styles from the line of \$250 "Lifetime" Longines watches. Now, however, this must be changed and, as conditions stand at present, First Prize Winners will be presented with \$250 "Lifetime" watches in the pocket style. Second Prize conditions have not been changed.

SATURATED SOLUTION

OCCASIONALLY the beginner comes across the phrase, "saturated solution," and wonders about its meaning. In preparing a saturated solution, a sufficient amount of the chemical is poured into a quantity of water so that some of the chemical is left undissolved. In other words, pour in a little more chemical than a given quantity of water will dissolve. The amount of chemical required will vary with the temperature—the warmer the water the more chemical will be needed; the colder,

By synchro-flash

such a largess of daylight. Such was our experience one day as we were synchroflashing an outdoor game. In order to get a good tone in the sky, we employed an orange filter. The picture was made as the use of the flash helped to balance the light between the shadow areas and the sunlight. We expect shortly to present an article on the general subject of synchro-flash photography.

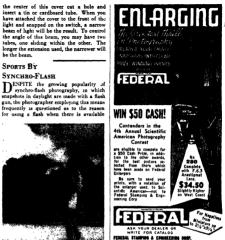

DUSTLESS TANK

REELS

THE popular Bakelite developing tank reels sometimes give trouble by collecting small dust specks within the grooves, thus causing undeveloped spots on the film. As the reel is revolved in the tank the dust is loosened and makes its way to the surface of the developing film and blocks development wherever it lands. One way of avoid-ing this is to give the loaded film a preliminary rinsing in water. But, of course, the best thing is to remove the offending dust and specks altogether. Drying the reels in a dust-free place is the way to do it. As soon as they have dried, they should be immediately put away in a closet or drawer.

tion throughout visible spectrum, increased | BOOKS marginal illumination of image. External appearance similar to Summar 50mm lens, except that diameter of front element is much greater New type optical glass used for front element, protecting lens surface against adverse climatic conditions. Special collansible sunshade available for Summitar as are the Lettz filters, in screw-in mounts.

LAFAYETTE HOME-MOVIE SCREEN: Crystal beaded screen reflecting four times light of ordinary diffusing screen over angle of 25 degrees. Wood frame also serves as base. Screen 30 inches high by 40 inches wide supported by metal post. Said to be free from halation, both in front and from sides. Weighs approximately six pounds.

MUNDER COLOR-FLASH LAMPS (30 cents each): For use with any daylight type film or plate indoors or outdoors Designed to produce illumination that has same color characteristics as bright sunlight. Also may be used with any tungsten or Photoflood type film. Munder No. 20B. 21 milliseconds to peak of flash; flash duration, 1/25 of a second; voltage required, 11/2 to 125 A. C. or p. c.: all lamps safety-coated.

LAPAYETTE "IN-SLIP" MOUNTS: Available in 22 sizes. Types for both horizontal and vertical prints. Openings vary from 3 1/8 by 3 3/4 inches to 10 1/2 by 13 1/2 inches. meeting needs for all standard size prints up to 11 by 14 inches. Mounts are of choice white antique finished material. Traced margin around window opening provides decoration. Another series especially intended for exhibition prints free from decorations of any kind, available for vertical and horizontal mounting of 8 by 10 and 11 by 14 inch prints.

ARGUS MODEL M CAMERA (\$7.50) · Takes single or double frame pictures, twelve 1 by 11/2 double frames or 24 single frames. Equipped to work as close as 24 inches. Shutter marked "dull," "cloudy," "bright," "sunshine," or "color." Triplet Anastigmat 1/63 color corrected. Uses specially spooled Dufaycolor film and new 35mm Arguspan film.

F-R "Special" Adjustable Roll Film TANK (\$1.85; double flange, 50 cents extra): Made of Bakehte, with stainless steel parts. Adjust-able to all popular sizes roll film from complete 36-exposure 35mm roll up to and

reel from either inside or outside (or both when loading more than one roll). Because of inside loading feature, films may be developed in rapid succession prespective of how wet reel may be. Only eight ounces of solution necessary for 35mm roll; total capacity of tank 16 ounces for largest size film. Revolving light trap stops light from entering funnel and aids quick filling and distribution of solution over film. F-R patented check stop prevents film unrolling during agitation. Double flange permits developing two full length rolls of 35mm. Knurled agitating ring built onto reel; permits thermometer to be used during deve ment and agitation.

BOOKS o r

Amateur Photographers

New Ways in Photography, by Jacob Deschin. Eminently practical from every point of view, this new book contains nothing of theory and nothing that the advanced amateur photographer will not find valuable in one way or another. It covers the whole range of amateur photography, discussing such things as trick ph tography, photomurals, retouching, infra-red, and a number of other sub-divisions that will not be found elsewhere in as clear and concise a man-

So You Want to Take Briter Pic-Tures, by A. P. Peck. A friendly, face-to-loce chat with the camera owner who has his developing and printing done at the photo shops, yet wants to know enough about his camera and its uses to enable him intelligently to utilize it to best advantage. Over 200 pages, dozens of illustration, \$2.10.

Universal Photo Almanac and Mar-KET GUIDE. How, when and what to photograph in order to make money with your camera; where to sell dif-ferent types of prints. \$1.00.

AMATEUR FILM MAKING, by George H. AMATRUR FILM MAKING, by George 11. Sewell, A.R.P.S. Useful to the begun-ner as well as the expert movie maker. Tells about films, cameras, exposure, film editing, story telling with the camera, and so on. Illustrated. \$1.60.

CHAMPLIN ON FINE GRAIN, by Harry Champlin. A complete hand-book on the entire subject of fine grain, in-cluding formulas and how to com-pound and use them. \$1.85.

PHOTOCRAPHIC HINTS AND GADGETS, by Fraprie and Jordan. How to make all kinds of photographic accessories; from film clips to cameras to light-ing equipment, and so on; 250 articles and nearly 500 illustrations. \$3.60.

PORTRAIT PHOTOGRAPHY, by H. Wil-liams. Fundamental principles of composition and lighting, paving the way to satisfactory results in this particular branch of photography.

PHOTOGRAPHIC ENLARGING, by Frank-PHOTOGRAPHIC ENLARGING, by Frank-lin I, Jordan, F. R. P. S. One of the most interesting and authentic books on enlarging. Its 224 pages cover every phase of the subject and 75 illustrations, many of them salon-soinners, show the value of correct technique. 33.60.

JACOB DESCHIN, conductor of our "Camera Anglen" department, mill answer in these columns questions of general interest to ansate up those raphers. If an answer is desired by mail, enclose a stamped, addressed envelope. Querest should be specific, but Mr. Deschin cannot understood to draw comparisons between manufactured products nor to advise on the purchase of equipment or materials.—The Edition

Q. I have heard that the backs of negatives may be so treated as to permit working on them in order to modify the image. Will you please explain how this is done?—C. S. K.

A. Prepare the following formula: 18 grains andarac Mastic 4 grains Ether Benzol 80 to 100 minims This is spread evenly over the back of the When dried, the resulting matter negative. permits the application of charcoal or crayon for the purpose of intensifying details or masses, adding clouds, and so on. The fineness of the matte surface is determined by the amount of benzol used, the greater the amount, the finer the surface obtained.

- Q. How long does it take for brown stains to appear on a print that has not had the hypo properly washed out of it?—F, L. D.
- A. No definite answer is possible, for it will depend on the amount of hypo left in the print and might take a few months, a few years, or longer. Of course, you know that various tests are available for determining whether a print has been washed free of hypo.
- O. I have been trying to use my camera, which takes vest-pocket film, for copying the printed matter in books, magazines, and so on. Employing Mascda (not Photoficod) Illumination and the standard orthochromation and the standard film of the standard film grain developers has attacked film grain developers has reproved unsatisfactory, the enlarged prints being grayish and muddy from also of contrast even when a hard paper is used. Would you advise getting a Simm samera so that I may use the standard of th
- 4. For best results, showing clean-cut reproductions of the printed matter copied, positive film will be the most satisfactory. Development in the contrast developer D-11 at 65 degrees for five minutes, should prove

The fault has not been in your lighting,

which is probably satisfactory, provided it is evenly distributed over the surface to be copied, but in your choice of film. In this type of ower host only do you have no need of the color sensitivity of orthochromatic and panciromatic films, but this actually is a deterrent to satisfactory work. You might yith suggestion contained in the least sentences to the contract of the co

Q. Infra-red film with filter calls for 1/20 of a second at f/3.5. I have a Goerz Dagor f/6.8 lens. What will the exposure be for this lens at its widest opening?—M. S.

A If the exposure you cite for \$\frac{1}{3}\$ opening is correct, the exposure at \$\frac{1}{6}.8\$ will be four times as long, or, in this instance, \$1/5th second.

A. The fina cannot be used as it atmost because the Tears is of the so-called non-symmetrical type and therefore requires the use of all flour elements which comprise the Teastr. The six-exposure roll is not now available in this country. By some expermentation, it is quite possible for you to waitable in this country. By some expermentation, it is quite possible for you to ploy the 120 or similar roll-fini site. The number markings on the back of the safety paper now include three rows, the left for the E-exposure style camera, the right for no called vest-pocket, 16-exposure cameras constitutional camera, because the Por your particular camera some causes and the content for your particular camera some constitution of the property of the

Our Book Corner

THE Book Department of Scientificamericanis conducted, with the co-operation of the Editors, to make available for you as comprehensive book service. Each month the Editors select and review in available titles, including prices. When these columns new books in a wide inquiring about books, please be range of scientific and technical fields. ddition, they are ready at all times to advise you regarding the best avail-

specific; remember that we can be of the greatest help only when you tell us just what you are looking for.

A successful engineer himself, with a nationally known corporation, the volume is built on his wide experience and observations. In content, it runs from a chapter: "Eco-nomics and the Engineer," through the whole range of engineering and industrial whole range of engineering and industrial activities to a chapter entitled "The Engineer as a Citizen," and a further note on "Economic Studies." (463 pages, 6 by 9½ inches.)—\$4.10 postpaid.—F. D. M.

OF ANTS AND MEN By Caryl P. Haskins, Ph.D.

A STUDY of the life of ants, especially with regard to their similarities with another social animal-man. Not a light, popular work and probably best suited to readers having a little previous knowledge of ants. (244 pages, 6 by 9 inches, 15 il-lustrations)—\$2.85 postpaid.—A. G. I.

THE BOOK OF INDOOR HORRIES By Emanuele Streri

TERRARIUMS, window-box garucinus, roof gardening, dish gardening, collecting cacti, aquariums, feathered pets, pottery plantics, pewtercraft, soap carving, chip carving, etching, and bookbinding—these are the indoor hobbies dealt with, chapter by chapter, in this book, about which one terrarium-aquarium-gardening hobbyist close to this reviewer says the treatment is practical and obviously prepared by an author who writes from his own experience. It makes a big difference in a book whether this is the case. (430 pages, 6 by 9 inches, 196 illustrations.) -\$3.10 postpaid .- A. G. I.

MAN AGAINST MICROBE By Joseph W. Bigger, M.D.

T would be difficult to write a mor IT would be difficult to write a more lacid, more directly revealing, popular yet scientific, account of the rudiments of bacteriology than this book which this reviewer read from beginning to end as a pleasure and not as a task. It tells what microbes are, how they are cultured, identification of the read of the rea microbes are, how they are cultured, identified (just enough insight into the intricacies to show the reader what it is that the mysterious bacteriologist doe, without bogging him down with details); also what microbes do and the main points about immunology—toxins, antitoxins and so on (again just enough to satisfy the reader who wishes a clear elementary understanding without trying to bocome a bacteriologist or immunologist). It also talls the long story of man's conquest of microbes, and it winds up with a lengthy discussion of practical applications of hacteriology in everyday life. A measty work. (306 pages, 5 by 7% inches, 55 illustrations.)—\$2.50 postpaid.—A. G. J.

THE STORY OF SURGERY By Harvey Graham

UNDER the pseudonym of Harvey Graham, a prominent British physician has written this story of the long evolution of the art of surgery from early times to our own days. Almost throughout, the reader own days. Almost throughout, the reader will shake his head and marvel at what men once thought was beneficial. The scope is best suggested by some of the chapter heads: Greek and Roman surgery; surgical renaissance; the black death; barber surrenaissance; the black death; barner sur-geons and chirurgeons; corpses, curiosities and quacks; a one-man revolution; sur-geons become gentlemen; the quacks and the brothers; John Hunter; struggle for corpses; death of pain; Lister; after Lister; today and tomorrow. The author knows tive: a live book. (425 pages, 6 by 9 inches, 23 illustrations) -\$3.85 postpaid.-A. G. I.

WONDER PLANTS AND PLANT WONDERS

By A. Hyatt Verrill

ODDITIES of the plant world—plant giants, intelligent plants, plants that sail seas, magic plants, plants with strange uses, plants that grow while you wait, and so on-is the central idea of this fascinating book by a world traveler who has brought together within two covers practically all the legitimate wonderlore of plants. Many scientists are likely to balk at the chapter on intelligent plants, particu-larly the account of the tamed, pet, sensitive plant that apparently knew the author and plant that apparently knew the author and trusted him so completely that it did not bother to close its leaves in the usual de-fense—a "one-man" plant. (296 pages, 5½ by 8 inches, 71 illustrations.)—\$3.10 post-paid.—A. G. I.

SIMPLIFIED HOUSEHOLD MECHANICS

By A. Frederick Collins

COMETHING more than the usual "how to fix a leaky roof" book for the house-hold mechanic has been turned out by this prolific writer of books for the handy man-In this latest of his products, he presents simplified explanations of how the mechani-cal and electrical equipment of the average home is made, how it works, and semething of how it is kept in operation. It enables

SCIENTIFIC AMERICAN 26 West 40th Street New York, N. Y.

ATOMS IN ACTION

By George Russell Harrison

APPLIED physics is the scope of this most readable volume by a professor of experimental physics and director of the research laboratory of physics at The Massa-chusetts Institute of Technology. Physics chusetts institute of Technology. Physics in agriculture; applications of the physics of sound; glass; electronics; radio; spectroscopy (this chapter appeared as pre-publication articles in the September and October numbers of Scientific American); physics in medicine, optics, television, music, air conditioning and aviation-these give the general scope. The treatment is the oppo-site of technical; your mother or sister could follow it easily to learn what these things are about-without being asked to learn too deeply. The author has a wide reputation as a facile expositor of applied science. (370 pages, 5½ by 8½ inches, 19 illustrations.)—\$3.60 postpaid.—A. G. I.

NEW PATHS IN PHOTOGRAPHY Ry Andreas Feininger

"OFF the beaten path" may be a trite expression but it surely applies specifically to this newest book on creative photography. The author first discusses va rious phases of photographic operation and processing, an understanding of which is necessary for an appreciation of the 47 full-page plates which follow. With this book as a guide, or as an inspirational source, the photographer will find the way open to unusual camera effects. (10\% by 11\% inches, 15 pages of text, and 47 plates.)—
\$2.85 postpaid.—A. P. P.

APPLIED ECONOMICS FOR ENGINEERS

By Bernard Lester

E XECUTIVES in industry have repeatedly pointed out that the technical graduate is handicapped by a lack of training in the practical principles of eco-nomics. The author of this book believes that the economic theories now prescribed for students are not applicable to present conditions in a practical way; hence this volume. In it, Mr. Lester has attempted to give (successfully, we believe) the sort of discussion which would quickly acquaint of discussion which would quiekly acquired the technical man with the principal prob-lems and human relations he should know if he is to conduct a business successfully.

FOR OTHER BOOKS YOU WANT, SEE PAGES 292 AND 310

the reader to understand more thoroughly the fundamentals of household equipment before he attempts to make repairs. (318 pages, 5 1/2 by 7 3/4 inches, well illustrated with drawings.)—\$2.60 postpaid—A. P. P.

ELEMENTS OF ORDNANCE

Prepared under the direction of Lt. Col. Thomas J. Hayes

IT would be impossible to give an adequate idea of the scope of this volume in this limited space. It is sufficient to state that the volume is a textbook for the use of cadets of the United States Military Academy and that it covers completely the questions of all ordnance manufacture from the smelting and refining of metals, construction of guns, the chemistry of explosives used, the types and uses of artillery, to the mathematics of ballistics. Projectiles, fuses, bombs, grenades, rifles, automatic and semi-automatic weapons, armor, tanks, and combat vehicles are also discussed. (715 pages, 6 by 9% inches, numerous illustrations.) —\$6.60 postpaid.—F. D. M.

SCIENTISTS ARE HUMAN

By David Lindsay Watson

E VEN the scientist himself finds it dif-ficult to think straight—logically, unemotionally-and this book is a fundamental critique of modern science, though it makes considerable demand on the reader's background. (249 pages, 5 by 7 3/4 inches.)
-\$2.35 postpaid.—A. G. I.

INDUSTRIAL SOLVENTS By Ibert Mellan

IT would be difficult to over-estimate the importance of solvents as there is hardly importance of solvents as there is hardly an industry in which they are not used to some extent. This comprehensive volume starts with theories of solution, discusses all the aspects of industrial solvents, and ends with a chapter on graphical expression and interpretation. (480 pages, 6 by 9 inches, illustrated, 267 graphs, 126 tables of properties.) -\$11.10 postpaid.-L. B. P.

THE SOCIAL FUNCTION OF SCIENCE By J. D. Bernal, University of London

AN examination, detailed and thought-provoking, of the unfortunate fact recently becoming more and more evident that science can be used not alone for man's good but destructively, as in war, and wastefully, as in inefficient institutions and methods of research; with recommendations regarding what could be done about it. (482 pages, 5½ by 8½ inches.)—\$3.60 post-paid.—A. G. I.

THE LIVING THOUGHTS OF DARWIN Presented by Julian Huxley, M.A., D.Sc., F. R. S., assisted by James Fisher, B.A.

DARWIN'S own writings make alow, difficult reading. The authors have therefore built this small book of carefully therefore bulk this small book of carefully chosen anoneyes from them, and tide them together with running pertinent comment. Thus the reader will be in first-hand touch with Derwin, yet without going through a year or two of dow plodding through all his weitings in life join the main substance. (III pages, eff. by 7 inches, one illustration.)—III begins of the properties.

TELESCOPTICS

A Monthly Department for the Amateur Telescope Maker

Conducted by ALBERT G. INGALLS

N OW that the amateur telescope making hobby has thrived for a dozen years since this magazine gave it wide scope, there are numerous amateurs who can downk of professional grade—sometimes even better, since the amateur, unlike the professional, can afford to put an unlimited

Figure 1: Holcomb's heavy mounting

amount of time on an optical surface until it as searly species as any optical surface can be made. In a few communities such an anstears or groups of amateties have concluded or are concluding arrangements with cooled educational institutions—high schools, colleges, universities—to make and install electropes for their mutual advantage. For example, the educational institution concludes the ending of the contract of the contr

totten, and, to local townsment).

The 12" reflecting telescope shown in Figure 1 was made by an amateur, J. M. Holcomb, 40 Clarke St., Burlington, Vt., for St. Michaels College in Burlington's suburb, Winooski. Asked to describe it, Holcomb states'

"The mounting is compact and rigid, operates smoothly, and is convenient to use. The setting circles are divided to half degrees and are illuminated. The driving clock (Figure 2) is run by a synchronous motor and is adjusted to sidereal time. The mounting is also provided with alow motion controls, that in declination being manual, that in right ascension motor driven.

"The building (Figure 3) consists of a 12" by 26" classroom on ground level and a wooden-framed, metal-sheated dome 12" in diameter, 9" high, above. The telescope resist on a ten-ton reinforced concrete pier entirely free from the building, in order that no vibrations may be transmitted to the telescope

"I believe the unit can be termed an amateur job, despite the fact that I did not actually lay the bricks, mux the concrete, or pour the iron castings for the mounting. I did design it all, also made the patterns, supervised the masonry, and did the rest of the construction.

"The mounting contains a temporary 8" mirror made by Father A. Rivard, S.S.E., of St. Michaels College, but a 12" mirror is heing made."

being made."

The rugged proportions of Holcomb's

mounting design are worth close study. This telescope well not shave, a many do, when a fiy alights on it. A telescope mag-nifes its own vehations just in the measure that it magnifies the stars, hence whratons that remain wholly invasible to the direct look cause the stars to dance wildly to the look through the telescope. Thus is why ordunary enters for rugdity in machines, supports, and so on, are much tow week for telescope mounting design. A telescope mounting design. A telescope mounting design. A telescope mounting design. A telescope mounting design.

FIFTH in a long line of eight Newtonians rangang from 4" to 12½", and from //5 to //10, and built over a period of four years, is shown in Figure 4, with his maker and owner, John J. Stoy, 450 Hurt Building, Atlanta, Ca. In his letter Stoy Building, Atlanta, Ca. In his letter Stoy low Freeharr Observatory." The telescope is a 12½" of 1½, and the total weight of telescope and pier is 3350 pounds. The deging is conventional but unusually clean. "The polar axis counterweight," Stoy writes, we open to argument as to necessity, but it brings the center of mass to the center of and in keeping with principles of mounting design started by Porter in the treatise "Amada Making," fourth edition.

Figure 2: The electric drive

Close inspection of the figure will reveal a very amonth, clean declination are casting and union for tube attachment. These were cast in inco, from patterns made and donated by Fred Ferson, Bloizi, Mins, author of the chapter on molding and casting, in "ATMA," and a freed of Stoys, The upper end of the tube rotate. The tube is ventilated through an oversized cell with Spoint suspension.

How well your seribe recalls the day when Stoy received and began working the 12½" Pyrez disk for this telescope, which, it seems, was just as hit bubbly Daily thereafter the mails brought generous samples of the most competent old-fashioned southern cussin', but finally Stoy learned to defeat the bubbles and the profacility imperceptibly dwindled until, at last, he actually came around almost to loving Pyrez. Even now, however, you must smile when you sy "bubbles" within his hearing. (It is impossible to east Pyrez disks without some bubbles—early get it hot enough and fluid enough, because of its high melting point, for all the bubbles to rise—but the makers that the bubbles to bubbles to rise—but the makers that of the bubbles to disable high point of the point of the bubbles to disable high point of the point of the bubbles to the point of the p

THE following communication is from James G. Baker, of the Harvard College Observatory:

"In reading through the very interesting article by Hendrax and Christie in the August Scientific American the present writer has noticed some incompleteness that might cause ambitions amateurs a bit of graff. All the various types presented by the authors are certanally workable, but caution must be exercised in order that cameras constructed should not exceed in aperture that which is justifiable theoretically.

"The thick mirror type discussed (Figure 3, IX in the August article) is optically inferior to both the ordinary and the solid kinds of Schmidt camera, although still quite a good camera in itself. The authors have failed to point out that the position of the apparent center on the axis depends upon the angle that the incoming rays make with the optical axis, and that this type of camera does not possess the symmetry of the Schmidt arrangement. Just as in the case of the usual Schmidt the third order errors are zero, which fact insu good performance, but, optically speaking, the thick mirror is not aplanatic beyond the third order, whereas the Schmidt is aplanatic to all orders of accuracy. The practical effect of this lack of perfection is to limit the speed and usable field of the camera, as compared with the Schmidt in glass. By a suitable deformation of spherical mirror and intermediate refracting surface, one can obtain nearly Schmidt performance, but the required optical work is more involved. The Zeiss company has recently produced a thick mirror system involving only spherical surfaces that has a flat field. The authors of the August article have neglected to point out that, as in the case of the usual Schmidt, the thick mirror type has a curved focal surface, spherical and concentric with the spherical mirror

Figure 3: Observatory, St. Michaels

Figure 4: Stoy and his "Bessie"

face and should be made so. The authors state on page 119 that the speed of an i/0.66 camera can be obtained with the field and correction plate curvature of an I/I of the usual kind, but this is not correct. The depth of the correcting surface is exactly n times deeper, zone for zone, than for the usual Schmidt of the same physical size, and the usable field about n times larger, angularly, in the case of the solid Schmidt, and about the same in the case of the thick mirror system, all compared with the usual Schmidt. The letter n used above stands for the index of refraction of the glass of the thick mirror. The index of refraction that appears in the denominator of the expressions for the correcting surface will be that for the glass of the correcting plate, in the above thick mirror system. "The performance of the Schmidt in glass

is truly remarkable. The solid glass combination was discovered independently and was investigated through its fifth order image errors in May, 1938, by the present writer, and discussed at the October, 1938, meeting of the Optical Society of America. The solid Schmidt, I have heard indirectly from Bergedorf Bergedorf Observatory, in Germany, where Schmidt worked .- Ed] workers, was contemplated by Schmidt himself, some years ago. Sinclair Smith seems to have been the successor to Schmidt in coming upon the solid Schmidt, but the publication was delayed by his untimely death in May, 1938. The Bergedorf workers unfortunately concluded that the thick mirror type constitutes the only practical way of getting to the focal surface, as Hendrix o in the early stages of his work. Hendrix, however, has now provided an ingenious solution in the form of the folded type. An off-axis type provides another.

"Let us compare the solid Schmidt with the ordinary Schmidt of the same physical size, that is, with the same aperture and radius of the mirror surface. The focal length is 1/n that of the usual Schmidt, the speed n' greater, the depth of the correcting surface n times deeper, the size of the chro-matic aberration disk n times smaller at each wavelength, and the curvature of the field the same. The third order astigmatism, reintroduced by the central hump in the correcting plate, is slightly smaller than that for the usual Schmidt, and for both is numerically of the fifth order. The first error of importance in either the solid or the ordinary Schmidt is the variation of spherical abstration with angle. This defect is several times smaller for the solid Solmide than for the usual kind. The

THE RECENTERS

If you are tempted to jump from your first 6" telescope making job to a much larger size, the accompanying photographs and description by a worker who jumped

the other way and put his energies into refinement may be worth considering. It is a 4" made by L. J. Ashby, 437 Stone St... Kalamazoo, Mich., and by Mrs. Ashby, and is equal in both design and finish to professional work. Both, we say, since we have seen a few telescopes with very exquisite or even over-elaborated finish but poor design. Ashby, who has been a telescope maker for several years, writes:

"There are a few who want a really portable instrument-one which does not require several strong backs and a truck to handle and transport. My wife cannot conveniently carry around even a 6", hence this 4" Newtonian which carries easily in the family car and can be handled by a woman. Some details are: Mirror made by Mrs. Ashby, with much oral but no manual assistance on my part. No scratches. Tripod, wood. Set-ting circles, graduated 5 minutes and 2°. Slow motions in both directions—in R.A. by flexible shaft. Tube, aluminum, cork

lined for better temperature performance. Rack and pinion focusing. Level and com-pass for quickly allning polar saits. Finder, diagonal type, 72, 5° field. Eyepieces, 1°, ½°, ½° (after Clarke, in 'ATMA'). Field of view with 1° cycpiece, 1½°. Tube wt.,

111/2 lbs., mount and counterweight, 27 lbs. Cost, \$35. Time, 210 hours.

"This little telescope resolves con of Epsilon Lyrae with 1/2" eyepiece, Pr

After all, no beginner on his maiden teles cope should attempt so fine a job as the Ashbys' but should aim to equal its design for rigidity, especially at two vital places: on the declination axis near the tube, where a large cross-section is here seen, and in the plate between this axis and the tube. which is here amply thick.

A little telescope, but built like a watch.

ANOTHER TN (which stands for Telescope Gnut, socially correct designation for telescope makers,) who, after maktion for lesecope makers,) who, after max-ing the beginner's 6", did not scorn to drop to a 4" because of its portability, is G. F. Hofferberth, R. F. D. 3, Dayton, Ohio, a telescope maker of long standing and now owner of a 12" Cassegrainian. It has a tube of copper sheet which was rolled, the edges scarfed and silver-soldered. The finish ("engine finish") was done on a drill press ("engine finish") was done on a drill press with a rubber grommet, oil and emery. Hol-ferberth made the patterns and did the machining for the polar axis support and bearing and for the well-proportioned fork, but the very beginner—the absolute tyro— need not worry about such refenements as the latter, since easier methods are available.

TELESCOPTICS

(Continued from preceding page)

are all zero with exception of spherical aberration, as in the case of the usual Schmidt. The front surface of the solid Schmidt. The front surface of the solid Schmidt behaves as a single prism face, so that, for large field angles, a star photo-graphs as a very short spectrum. This defect is of no importance in spectroscopy, for which such a glass camera is most useful. The Harrard Observatory has under con-struction a solid off-axis Schmidt, for which the focal ratio has been pushed to the ex-treme of f/0.30. The focal length is 15mm, treme of 1/0.30. The local length is 15mm, and the usable field 3mm linearly, or about 11 degrees. The field is still larger for reduced aperture.

"A variation of the Schmidt in glass is

offered by converting the spherical mirror

into a spherical lens surface, with a corre sponding change in the depth of the correcting surface. Because of the small power of a lens surface of the same radius as a mirror a sens surface of the same radius as a mirror surface, as compared with that mirror, the aperture-ratio of this type camera is limited to //1.5 or slower. It is, nevertheless, a true Schmidt camera. The focal surface is spherical and concentric with the lens surface

cal and concentrie with the less surface.

"In the-article by Hendrix and Christic,
even for the folded type, they mention a
plane focal surface, and comit it among the
seven plane surfaces to be made. This is
inacourate, for the focal surface, as in the
nusul-Schmidt, is spherical and concentric
with the mirror, and should be made so.
"In the discussion of the Weight type,
which has a far field, the surface, state that
their //I was unsatisfactory. Separate
their //I was unsatisfactory. Separate

gether the complete story. The Wright type, in addition to having double the chromatic trouble of the Schmidt of the same focal length and sperture, has astigmatism of the third order, that seriously limits the field at high spertures. As the authors state, cameras of 1/3 and 1/4 are satisfactory for cameras of 1/3 and 1/4 are satisfactory for imited fields, but then there is no need to make one in glass. For spectrographic pur-poses, the Wright type, called specifically the "short" type to distinguish it as one of a family presented by Wright, also has a curved field, and on that surface third order astigmetism along the spectrum is zero.

"The present writer would like to caution the amateur, who is contemplating a very fast camera, to compute his correcting surface from the more accurate formulas given by Wright in 'ATMA,' and to try contacting some person who has made a Schmidt to some person who has made a Schmidt to check the computation. If the amateur makes a solid Schmidt, he should use the ordinary formulas for a correcting surface, but with a factor of n, the index of refraction, throughout, so that the correcting plate is n times deeper, zone for zone, than is the case for the usual Schmidt. Moreover, the position of the focal surface must be carefully computed.

"Hendrix and Christie mention that the cassest form of correcting plate to make is one for which center and edge are at the same height; that certainly must be correct from their wealth of experience and prac tice, but I would like to point out that the departure from the nearest sphere (one through center and edge) is nearly independent of their parameter k and, therefore, that the amount of aspherical figuring is likewise nearly independent of k.

"The above is in friendly criticism, with

an eye toward aid to the amateur, and in no way should detract from the excellence and usefulness of the article as a whole."

In his letter of transmittal, Baker states that he has the entire set of quantitative formulas that bear on the Hendrix and Christie designs and will be willing to cooperate with any amateur desiring information, who is really serious about making matton, who is really serious about making some of these telescopes. In each case, he states, the many factors should be carefully balanced before the maker starts pre-ciptionally on a part not justifiable theo-retically. He will give information to any-one wishing to know about the performance of a Schmidt of given specifications, or will recommend apecifications to fit a given need. He has also designed a family of flat-field cameras, equivalent in performance to the Schmidt camera, which he described before the American Astronomical Society last sum-

Priority on (1) the fact that the correcting lens of a Schmidt should be made larger than needed and masked out, to facilitate the work, (2) the use of a liquid on the correcting lens while it is ground to shape, also use of a pattern of straight lines at the plate holder, and (3) the interpretation of the zones by the method just described, all described in the Hendrix and Christie straight lines at the straight lines at the zones by the method just described, all described in the Hendrix and Christie straigh of the Art. atticle of last August, is claimed by Arthur De Vany, 727 Sylvan Court, Davenport, lows. In letters offered this department for lows. In letters offered this department for publication leng ago, De Vany described these methods. Owing to your scribe's pro-crastination in publishing them they were offered to Populer Astronomy, which pub-lashed shem a year or so ago, and it is now desired to meation the matter in order as far as possible to racks amends.

TRADE MARKS

and UNFAIR

COMPETITION

By ORSON D. MUNN

A TRADE MARK is an intangible asset of a business, yet its actual value may grow so large that it becomes the very foundation on which depends the whole structure of the business. Because of this fact, every business man should have available such information on trade marks as will enable him to judge with a fair degree of accuracy the desirability of any mark which he may be considering.

Here, in one handy volume, written in non-legal terms, is a simple yet comprehensive interpretation of the Federal statutes and the body of common law relating to trade marks and unfair competition.

PATENT CHANGES

THE changes made in the Patent Law during the last session of Congress were designed primarily to shorten the period between the completion of an invention and the issuance of a patent covering the invention. The most important change in the law relates to the very important two year period. Heretofore a patent application could be filed within two years of the first publication of an invention or within two years after an article embodying the invention was placed on sale or went into public use. Under the amendment to the law the period of two years is reduced to one year after August 5, 1940.

Another amendment which is corollary to the above amendment and which goes into effect on the same date relates to the practice of copying claims from issued patents for interference purposes. Heretofore a person claiming to be the inventor of certain subject matter covered by an assued patent could copy the claims of the issued patent within two years of the date thereof. This period has now been reduced to one year.

Another important change, which became effective on October 5, 1939, relates to the simplification of interference practice. An interference is a proceeding before the Patent Office between two or more claimants for patents on the same subject matter to determine which claimant is the prior inventor. Interference proceedings are necessarily involved and frequently consume great deal of time through no fault of the Patent Office, with the result that the issuance of the patents involved is delayed. Prior to the change in the law, interference proceedings were heard in the first instance by an Examiner of Interference. An appeal could be taken from his decision to the Board of Appeals of the Patent Office and an appeal could be taken from the decision of the Board of Appeals to the Court of Customs and Patent Appeals or in the alternative a suit in equity could be filed to compel the issuance of a patent. The inter-mediate appeal to the Board of Appeals has now been eliminated and the interference is heard in the first instance by a board of three Examiners of Interference rather than a single Examiner of Interferences. A fourth amendment to the law empowers

the Commissioner to require a responsive pending patent applications in a shorter time than the six months previously allowed

time than the six months previously account by the law but under no circumstances in less than thirty days. A fifth amendment abolishes so-called re-newal applications. Heretofore upon the allowance of a patent application the appli-

cant had six months within which to pay the final government fee. If he failed to pay the fee within that period the applica tion became forfeited subject to renewed in an additional six months period upon the payment of another government fee. The original intention of the renewal provision of the Patent Law was to permit a poor inventor who could not afford to pay the final government fee an additional period of time within which to obtain the necessary funds. However, it has frequently been charged that the renewal provision of the statute was utilized by wealthy companies and individuals to delay the issua of a patent and thereby prolong the effective period of the monopoly. The renewal provision has now been abolished and the Commissioner of Patents now has the discretion to receive the final government fee if paid within one year after the expiration of the six months period allowed for the payment thereof.

The sixth amendment to the patent law is intended to increase procedural efficiency and provides for transferring jurisdiction over the registration of copyrights on commercial prints and labels from the Commissioner of Patents to the Register of Copyrights. The provisions of this amendment become effective on July 1, 1940.

ATTIMINUM

FROM time to time rumors have been circulated as to the injurious effects resulting from the use of aluminum coo ing utensils. It is interesting to note that the Federal Trade Commission has taken cognizance of these rumors and has filed a complaint against the publisher of pamphlets dealing with this subject, charging that the representations contained in the pamphlet deceive the public.

The titles of the pamphlets involved are "Poisons Formed by Aluminum Cooking Utensils" and "Are You Heading For The Last Round Up?" According to the Commission the pamphlets contained such statemission the pamphiets contained such state-ments as these..."A friend of mine, after having seventeen carbuncles, threw out his fancy aluminum ware. The carbuncles dis-appeared"; also "Another fed his dog from an aluminum dish; the dog died from cancer of the face.

JOINT OWNERSHIP

THE weakness inherent in the joint ownership of a patent is illustrated a ownership of a patent is illustrated by a recent suit for patent infringement. The suit was brought by the co-owners of a patent for a non-refillable drum for lubricating oil against a prominent oil refining company. The Court found that one of

the co-owners of the patent had previously entered into a contract with the oil refining company wherein he had granted a license to the company to use the invention covered by the patent. The usual rule of law app able in such cases is that a good and valid license may be granted by one of the co-owners of a patent and thereafter the licensee is not liable to pay damages or profits for patent infringement to the other

In the case in question it was argued by the co-owners that a different situation existed because of a contract between the co-owners whereby each agreed not to dispose of his share in the invention without the written consent of the other. This agreement, it was contended, rendered it impossuble for either of the co-owners to grant a license without the consent of the other. The Court concluded that while the agreement was no doubt binding between the parties it was not binding on the oil refining company in the absence of notice of the agreement. The Court found that as a matter of fact the oil refining company did not have such notice and that accordingly it was licensed to practice the invention covered by the patent.

GOLD MEDAL

THE Commissioner of Patents has ruled that the words "Gold Medal" are not descriptive of various items of merchandise or of their characteristics or qualities.

This rule was handed down in connection with the application for the registration of the words "Eventually Gold Medal" as a trade mark for poultry, dog, and cat food The Examiner rejected the application or the grounds that the words "Gold Medal" "descriptive of various items of merchandise that have competed successfully in expositions or contests and awarded gold

An appeal was taken to the Commissioner of Patents who reversed the decision of the Examiner, holding that the words "Gold Medal" were merely suggestive of the characteristics of the merchandise and not descriptive thereof

FOREIGN COMMERCE

THE Federal Trade Commission has re-Leently shown an interest in unfair methods of competition in foreign com-merce. Thus, it has issued a complaint against an importing and exporting company charging that the company had induced a Japanese manufacturer to misbrand Japanese-made optical lenses and falsely to pany is also charged with procuring foreign mark them "Made in U. S. A." The comusiness by "negotiating the export of such falsely branded products to Cuban

The Commission alleges that purchasers in certain foreign countries, including Cuba have a preference for products made in the United States as distinguished from like products made in Japan, and that these countries grant reductions in import and custom duties on products made in and imported from the United States. Under the circumstances the Commission charges that the company's practices are unfair and react to the prejudice of competitors and to the prejudice and injury of United States manufacturers of optical lenses.

How to get rid of an

INFERIORITY COMPLEX

A true story of a man who found that self-confidence is not a matter of education or luck

HE WAS GOOD in his job No one denied that But he felt inferior to his associates Most of them were college men He envied them the mysteriousthing called "background"

Today he happens to be one of the principals of the business. But more important, he has lost his inferiority complex Instead of envying his once better informed associates he is their equal.

His case is by no means unusual He has learned the secret that the reading of great literature opens the gateway of the mind and offers a broader view of life. This broader view inspires self-confidence. In a word, it's culture.

There are thousands of men today who lack the essential background so mecessary for success in every field of life and who don't know where to turn for it. The cold stone front of a public library suggests groping among thousands of books." What are the really great books?" you ask

DR. ELIOT'S FIVE-FOOT SHELF OF BOOKS THE HARVARD CLASSICS

The question has been wonderfully answered by America's greatest educator, Dr Eliot, forty years president of Harvard. He made it a vital part of his great life work to assemble in one set the really worthwhile writings. These books place you on an equal footing with the best educated of your associates.

LIBERAL EDUCATION AT YOUR FINGERTIPS

This supreme library of 418 immortal masterpieces is unified into a living, powerful educational force by the marvelous working index containing 76,000 entries, guiding the reader to an understanding of world culture

The Harvard Classics is now offered at the lowest price in its history. The cost per volume is actually 1/3 of that of the ordinary current novel.

Due, however, to continually rising manufacturing costs, we expect these prices to be effective for only a limited time—SO WRITF TO-DAY FOR INFORMATION.

THIS FAMOUS LITTLE BOOK FREE!

FIFTEEN MINUTES A DAY always finds a cordual welcome on library tables. Thousands of modern people have read it from cover to cover with absorbing interest. It gives Dr. Eliot's own plan of reading. It is packed with helpful, practical information. You really can't afford to mass this little gen of literature. You'll receive this beautiful book without charge after you fill out and mail the coupon below.

NO one needs to be reminded of the important part played in moderns warfer by the siplane; newspaper stories are a constant reminder. The other side of the question, that of defense against the frightfulness of air raids, is equally important. It is vital to every nation that anti-aircraft guns be provided in efficient types and large numbers. The United States is, therefore, rapidly adding to its acres of guns, for defense against attacks from the akits by a possible future enemy. Rapid and accurate fire characterize this deadily weapon for defense.

Personalities in Industry

THE automobile business has made the most amazing progress of any industry in the past two decades—and the least known part of it—the human aide—is one of the most fascinating stories in American business. For the automobile industry is literally a selfmade business. Perhaps a very good reason for this is because it has been built—and is being operated today—by self-made men, of whom Byron C. Foy is a good example

Mr. Foy is president of the De Soto Motor Corporation, vice-president of the Chrysler Corporation, and secretary of the Automobile Manufacturers Association. And he started at the bottom—but he's never forgotten the things he learned about people when he was out on the firing line as an automobile salesman in the days when you not only had to sell a man a car, but also sell him the idea of why he ought to own a car at all!

As far back as college days, Byron Foy was what you might call an "automobile nut". He had a little four-cylinder car and he lowed it. In fact, he liked cars so well that when he graduated he went to work as an automobile salesman in a Dallas factory branch, but he didn't wait around the sales floor for people to come in. He went out and made calls Lots of them.

When the company announced a nation-wise also context, Foy decided the would have to sell in volume, if he was to compete against aslessmen in the larger cities. Thus he went out after foste business—large corporations and the city itself. Like the rising young main in the popular Alger novels of the third day, Byron Foy won a coveted prize in that context.

Then the factory sent him east as a traveling representative His eastern dealers said they couldn't sell cars in winter. "We can't make country deliveries in the snow," his men complained "Why not deliver the cars on sleds"

BYRON C. FOY

Foy suggested. And they were delivered, right to the farmers' front door. Sales increased

Still later Fow went to the Pacific Coast and subsequently became presdent of the Reo Motor Company of California Later he returned east as a partner in the New York Chrysler distributorship.

Here he came to the attention of Walter Chrysler, noted for his encouragement of young blood in his organization. Walter Chrysler recognized Foy's promotional instincts and sound busi ness judgment, and brought him to staff headquarters. Under Fov's leadership. De Soto has become a potent factor in Chrysler Corporation sales, and when you talk with Byron Foy, you'll know just why. The fact that he knows people-the things they want and the motives that make them buy-is reflected in his talk, as well as his products, his advertising, and his relations with his men and his dealers.

There's nothing fancy about Byron Foy's office, or about Byron Foy The office is simply furnished. Papers never stay on his desk very long Foy is a bear for detail- but he goes straight to the most important tasks first talks easily, and he is easy to talk to-He believes in giving his executives complete confidence and responsibilities. Thus he not only surrounded himself with a strong staff, but the way in which he operates has helped make them strong Byron Foy is married, and has two children. Besides his family, his main hobby is still motor cars Though for sheer exercise he rides horseback. the wheel is still his first love. De Soto salesmen in New York know that they can always "call Mr. Foy's office" when a little extra help is needed to make a De Soto sale to one of Foy's many friends. For Byron Foy, automobile company president, is still a great automobile salesman who gets a kick out of "closing a deal."

50 Years Ago in . . .

(Condensed From Issues of December, 1889)

CANNON—"The Spanish government, determined to emancipate the country from its dependence upon foreign nations for its munitions of war, has of late years displayed great enterprise in the establishment of works for the building of war ships and

cannon Among the guns lately turned out at Trubia are four which form part of the armament of the new Spanish steel cruiser Pelavo Of these two are 49 ton 13 in guns and two are Il in One of the 49 ton guns, shown in our en graving, was lately proved The projectile used was of steel, weighing 960 lbs., fired with a charge of 440 lbs. prismatic powder, which gave an initial ve locity of about 2000 ft

per second and a pressure near 20,000 lbs per square inch. The penetrating power at short range is 32 in of wrought iron. Length of gun about 40 ft."

TRANSATIANTIC. "The steamer (a) of Rome, on her last trip out, made the port of Milford Haven instead of Leverpool, the magnificent system of docks, long under construction at that port, having been at last completed. The substitution of Milford Haven for Laverpool as a terminus saves the delay in steaming up St Georgia's Channel and up the Mersey, and, more important yet, avoids the dangers of the channel fogs and the amonying delayoff the Mersey Bar. To London from Milford Haven such the Severn tunnel in 285 miles, against 201 from Laverpool, it being 1½ hourlonger by rail"

COAL DUST- "Heretofore about one-seventh of the product of the coal mines has been lost in dust. It is now intended to utilize the dust by making it into bricks that will burn like hard coal, except that there are no clinkers as the bricks burn to ashes."

FORE-ST GLANTS—"Plying on Puget Sound is a boat 122 feet long. The timbers of which the hull is built run from stem to stern, and not one is spliced. As a specimen product a Washington lumberman sent to San Francisco last year a heam 24 inches thick, and 152 feet long."

PHEASANT—"The Mongolan Pheasant, a valuable addution to our native game birds, was imported from China a few years ago it has increased with surprising rapidity in western Oregon, Washington, and in the northwestern corner of California, under effective legislative protection. The plannage of the male is extremely brilliant and attractive. As a table dish it equals the partridge and prairie chicken of the Fast!

LUMINOUS FOUNTAINS "Among the most wonderful displays, electric and vasual, at the recent French exposition were those pertaining to the luminous fountains, which were arranged on a grand scale. The chameleon-like changes of color in the fountain waters were wonething autonishing to behold. It was not accomplished by the mere throwing of colored lightin upon the exterior published by the mere throwing of colored lightin upon the exterior of the water; the hearins of light heing, no re-press, thromostion of the water; the hearins of light heing, no re-press, thromostion and imprisoned within the crystal walls of the water and then carried along with it, becoming vs-lible by interior reflection during the discharge of the water."

PHONOGRAPH INSTRUCTION—"Edison's phonograph has scarcely, as yet, passed the period of "novelly and curiosity," but many practical applications of the instrument have already been suggested, and have in some cases been actually carried out There

is one application, however, that we have so far not heard mentioned, and that is the instruction in the pronunciation of forcing languages. In the future the publishers of manuals of instruction in foreign languages will find it, most likely, a paying undertaking to publish a phonographic key of the various exercises, thus enabling the learner to acquire the correct intonation of the property of the control of the property of peptal word or sentence until it has been perfectly mutted by homeseff."

LABOR SAVING—"Some people denounce labor-saving machines as an evil They notice that a few individuals are put out of work for a time by the introduction of some device, but they ignore the greater benefits which the whole community obtains."

LIGHTHOUSES.—"The Lighthouse Board has submitted its report for the fiscal year ending June 30, 1889, to the Secretary of the Treasury At the close of the year there were under control of the board 1021 lighthouses and lighted beacons, 1328 lights on Western rivers, and 4284 busys of varous kind. In the main tenance of these there are employed 1934 light keepers and a number of miscellaneous emblowed.

WAVES.—"The height of sea waves has long been the subject of controversy. In the recent Britah scientific expection some instructive data were gathered by a sensitive amendo harometer capable of recording its extreme rase and fall by an automatic register. With a sea not subjected to an atmosphere of unusual violence, it indicated an elevation of 40 feet from the wave-base to creat."

ARMOR-PIERCIN(—"The new British steel cruiser Blake is to be armed with handy rapid-firing guns that can penetrate 12 or 15 inches of armor plate."

FOOT-WARMER—"One of the latest applications of electricity is the making of a floor mat that throws out heat—an electric heater, in fact, in the form of a mat. An excellent device for warming the toes"

BALLOON MINES TO PUT THE AIR OUT OF ACTION

IF German bombers appear over London some dark night, they may find above, below, and around them an inescapable aerial mine field consisting of myraids of small, free balloons sent to a predetermined height and drifting with the wind. Each would support a cannister of high explosive on 40 feet of fine-steel wire. Enemy planes would, therefore, face the double danger of fouling their propellers with wire

and contacting the bomb itself. If a wire should catch on a wing, the bomb would be whipped backward to explode against the plane. A time fuse on the bomb allows it to become "alive" only after sade launching and puts it out of action after a given time. This aerial mine has certain dis actionafter a given time. This aerial mine has certain dis advantages, but it affords, according to H. G. Wells, "the possibility of putting the air out of action whenever we wish it." Invented by Major H. J. Muir, it would have an enormous effect on the morale of enemy raiders. Drawing courtesy The Illustrated London News.

Loading bombs in a U S. bombing plane during recent maneuvers

WILL BOMBS DOMINATE?

ERIAL bombing has become a naval A and military science of dominant importance in offensive warfare. This is attributable mainly to development in aircraft in regard to range, speed, and carrying capacity. Until near the end of the World War in 1918. aerial bombing was a very secondary means of offense compared with aerial machine gunning, which was organized for inter-aerial combat and occasionally used against troops deploying in the open. The airplane, at this time, was not a high-caliber offensive weapon. Today, the aerial bomber has become a supertype of long-range heavy artillery and a significant challenge is now being made to establish its efficiency not only against the strongest land fortifications but also against fleet battle-units and submarines. Recent events indicate that the command of the seas may to some degree be passing over to the nation which can hold command of the air. Should such power emerge, the aerial bomber will have become a primary offensive weapon in general warfare.

Aerial Bomber Has Become Super-Type of Long-Range Heavy Artillery . . . How Bombs Differ in Their Penetrating and Explosive Action

By ARTHUR E. OXLEY, M.A., D.Sc.

Multiple-engined heavy bombers, numbered internationally by thousands, can now carry projectiles, each weighing a ton or more, over land and sea defenses which are far out of range of the most powerful military or naval guns Such projectiles are equipped with armor-piercing devices for hurling on ships and fortified positions; they explode with a delayed action after penetrating the objective Other projectiles are equipped so as to produce a "scatter" effect over the widest range possible; they are designed to cause the greatest devastation in troop concentrations deploying in the open or on unsheltered civilian populations. Such

projectiles explode instantaneously on contact with the objective.

High-explosive bombs may be classifed in two general groups according to their penetrating and delayed explosive actions or their non-penetrating and instantaneous explosive actions. The first has a relatively thin shell and a penetrating nose-cap of sold steel; the second has a thick shell for more deviatating fragmentation effect and a blunter nose to counteract penetration. There are many types of bomb in each classification and those illustrated diagrammatically in Figures 1 and 2 are intended merely accumples to indicate the general difference in the two classes.

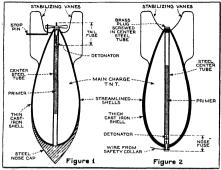

Figure 1 shows general details of a penetrating type of bomb, in which the fuse action is delayed Figure 2 illustrates a nose fuse type for instantaneous action

The type of fuse used in the bomb shown in Figure 1 is a delay fuse inserted in the tail of the bomb; that in Figure 2 is an instantaneous fuse fitted into the the nose of the bomb. (A delay fuse may also be fitted into the nose of a bomb but its construction must be different from the type shown.)

THE delayed-action bomb penetrates and is used in attacks on ships or on towns where the structures are several stories high and are more or less strongly reinforced. Such a bomb, if dropped from a height of 10,000 feet, strikes the object at about 800 feet per secondmore than 500 miles an hour. On striking, the bomb does not explode immediately. It penetrates the roof and may pass through three or four floors before the fuse explodes it. The reason for this delayed action is shown in Figure 3, a diagram of one type of tailfuse. The bomb can explode only when the striker-pin punctures the detonator cap. When the bomb is fused, the striker pin is held away from the cap by a collar to which is attached a pair of vanes. While the bomb is in its carrier on the airplane, these vanes are prevented from rotating by a stop pin fixed to the carrier (Figure 1). As soon as the bomb is released, the vanes rotate. owing to the rush of air past the bomb. After the bomb has fallen about 100 feet below the plane, the vanes fly off the screw-spindle. To prevent the strikerpin from prematurely piercing the detonator while the bomb is in the air, the striker rides on a coiled spring as the bomb falls. On impact, the bomb is slowed considerably while the plunger carrying the striker has nothing to stop it but the resistance of the spring. The merta of the striker therefore compresses the spring and, in a small fraction of a second after impact of the bomb, the pun pierces detonator and the bomb explodes. This small delayed action is sufficient, however, to allow the bomb, because of its terrific speed and penetrating cap, to pass 20 to 50 feet made a building, according to the nature of its construction, before explosion takes place. Thus the structure collapses from the pressure of the confined blast.

In addition to the objectives already cited, deep trenches and air-raid shelters may be successfully attacked by bombs so fused.

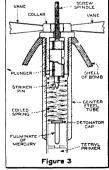

The instantaneous fuse used in the bomb shown in Figure 2 is designed to bomb shown in Figure 2 is designed to cause the greatest possible apread of the bomb fragments, by the explosive blast, so wer the surface of the terrain attacked, for the thick shell is shattered into chunks of metal which sweep over a wide area as the high-explosive is detonated. A type of nose fuse used for such a purpose is shown in Figure 4. The instantaneous explosion resulting is far more devastating to exposed personnel than would be the delayed explosion described above.

The nose fuse shown has no spring, Instead, a plunger is held securely in position by a copper pin, about 1/8 of an inch thick, which passes through the plunger and the walls of the fuse. While the bomb is in its carrier on the air-plane, the fuse is kept "dead" by a safety collar which is slotted and inserted between the body of the fuse and a pressure plate. This collar is attached to the bomb carrier (see Figure 2) and is a secure protection against premature detonation even should the bomber crash

on taking off. As the bomb is released. the safety collar is withdrawn. On impact, the pressure plate is arrested. The shock which it thus receives can be transferred to the detonator only through breakage of the copper pin which is incapable of withstanding the tremendous momentum of the whole bomb. The result is that the copper pin is instantaneously sheared off and within less than a hundredth of a second the striker nin pierces the detonator which causes explosion. Owing to the almost instantaneous action of this fuse, the explosion makes only a very small crater -perhaps one to two feet deep on average ground for a bomb weighing 100 pounds. Under similar conditions the same bomb, fitted with a tail fuse, would make a crater about five to six feet deep. Figures 5 and 6 show this difference. With a tail fuse, the bomb is almost buried in the ground on explosion and the blast is localized With a nose fuse, the homb is almost entirely above ground and its blast is wide-spread.

WHEN bombing from low altitudes, as was done over the countryside in Poland, an additional slow time-fuse must be inserted between the striker mechanism and the detonator. On release the bomb travels forward with the same velocity as the ampliane and the additional delay of at least several seconds, given by the time fuse, allows the bomber to get clear of the danger zone before detonation takes, place.

The main filling charge of modern high-explosive bombs is relatively insensitive. Tri-nitro-toluene (T.N.T.) and various mixtures of this with ammonium nitrate, itself an explosive, are the usual fillers. The mixtures are known as "amoto". Sometimes a small

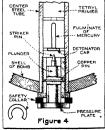

Details of a tail fuse

percentage of powdered aluminum is included in a filler called "ammonal" which has a higher temperature of detonation. Without the use of a detonstor none of these explosives will function even on impact of the bomb from several thousand feet. Even the detonator, containing a few grains of fulminate of mercury, which explodes violently on shock, is not a certain guarantee of detonating the main filling charge. It is customary, therefore, to employ a primer consisting of an explosive more sensitive than T.N.T. but less so than fulminate of mercury, to boost the detonator and effect the complete detonation of the filler. In aerial bombs, this primer is charged with "tetryl" (tetra-nitro-methyl-aniline). which, like T.NT, is a dye-works byproduct. The general manner of as sembly of detonator, primer, and filler is shown in Figures 1 and 2

FOR modern incendiary bombs, a most effective filler is thermit. This consists of a mixture of powdered aluminum and magnetic oxide of iron, and is commonly used in welding. When it is fired through a magnesium primer which in turn is ignited by a phosphorus coated friction strip, a temperature of from 2300 to 2500 degrees, centigrade, results-a temperature which easily melts steel Thermit does not depend upon a surrounding atmosphere of air for its action-the oxygen in the iron oxide provides this, uniting rapidly with the aluminum and causing the tremendous rise in temperature The mixture will burn under water, boiling it fiercely. Water is uscless to extinguish the whitehot slag-it merely passes into scalding steam. Sand is best for localizing the incendiary action

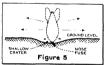

Modern incendiary bombs are very small: about six inches long and threequarters of an inch in diameter. They are provided with heavy penetrating iron nose caps and small fixed tail vanes. Containers, each filled with several hun-

Details of a nose fuse

dred bombs, are discharged as units. On their downward flight they scatter, since they are poorly streamlined, and cover a wide area of the objective. Hundreds of fierce small fires are thereby started, and any attempts to control the general conflagration are made extremely difficult owing to the numerous scattered outbreaks. If such an incendiary raid is immediately followed up by a raid with high-explosive bombs, and possibly also a gas attack, no fire personnel.

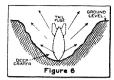

Among bombs used in gas attacks, the most effective are those filled with "mustard gas," which is a liquid. When burst by a small powder charge, the heavy liquid diffuses into the ground and, for days after the attack, is danger-too to anyone in the locality. Where the temperature rises locally, unexpected vapors emerge and may descend into the deepest dugouts and shelters. This avapor acts is dowly on the eyes and lungs it has practically no smell and long after a raid unsuspecting persons who

A bomb fused at the nose explodes on contact, spreading a wide blast

chance to remove their gas-masks—as they must do sooner or later, either for nourishment or comfort—may be attacked without warning. Some hours later blurred eyes, lump bodies, and severely blatered skins show the results. This gas causes only a low mor talliry but it as highly efficient in putting personnel out of action.

As the war develops, it is possible to make only a guess as to the limits to which chemistry and physics will be applied as aids to serial "frightfulness. Rumors of the use of super-high-explosives spread 'round the world during the later aerial bombardments in northern Spain. Liquid oxygen was suspected as the component Cylinders of cellulosic material when dipped in liquid oxygen become virtually packages of dynamite and when freshly prepared have enormous detonating power But other attendant circumstances, particularly those relating to the high vulnerability of such explosives to shell and even bullet fire and to the evanescent power of the charge-due to continuous and unpreventable evaporation of the liquid oxygen-would seem to lessen the likelihood that such liquid-oxygen matrices could be of real military effectiveness. True may be the report

Penetrating deeply, the blast of a tail-fused bomb is more localized

that the explosive used was "obtained from the air"—but so are the ammonia ingredients used in "amatol" and "ammonal" high explosives obtained by the nitrogen fixation process.

There is also the possibility that concentrated effort is being made to seek a practical application of what has been called the greatest scientific discovery of the year—the detonation of atomic energy as exemplified in the selfcatalyzing fission of uranium and other substances we neutron bombardment.

LAST, we cannot completely ignore the possibilities of biology. Reports are available that much experimental work has been done on the possibility of employing bacteria as a novel kind of "ammunition." In this connection, Wickham Steed has called attention to the activities of the aerial offense section reported in Luft-Gas-Angriff of the Berlin War Office. In 1938, General Chu Teh reported to the League of Nations that the Japanese had used bacteria in four central China provinces. These present impracticability or the dangers which attend such desperate means, but modern civilization cannot entirely shut its eyes to the possibilities of future research in this field. The biological view indicates that the effective dissemination of a bacteriological fog of typhoid, anthrax, spotted fever, or plague would have to be carefully synchronized with exacting conditions of temperature and humidity to insure survival of the germs. The bacterial "bomb" apparently consists of a glass container filled with a prescribed culture which is floated by parachute control over areas far in the rear of enemy lines, a mechanical release being employed to release the contents either in the air or on ground contact. The available reports also indicate the "conscription" of infected vermin.

If such monstrous methods should ever that the become practicable it appears that the become practicable it appears that the conjy means of defense both for the attacker and attacked would be an elaborate organization of all resources of prophylaxis. Probably a mere knowledge of the power of retaliatory edge of the power of retaliatory prove practicable, will be an adequate deterring against such attacks.

ALL FOR ONE AND ONE FOR ALL

T is customary to think of that large group of companies which provides motor transportation for America. and for much of the rest of the world, as units in a number of industries-automotive, aviation, oil, tires, parts and accessories, and so on. Actually, this entire group is one inter-related, interdependent industry, the problems and progress of which are inseparably linked Nothing illustrates this so well as their co-operative research activities. It is doubtful whether anything in American industrial life during the past ten years has been more significant than the freedom with which research men in this group have exchanged ideas and cooperated in experimental projects.

The fruits of this research have had a far-reaching effect. Better cars at lower prices, better gasolines at lower prices, better tires, airplanes. trucks, tractors, stationary engines, motorboats, and other products made by these companies have been in such demand in America that this closely associated group has grown to a point where it now employs the full-time services of between six and seven million people; furn ishes bread and butter for a sixth of the nation directly, and a considerably larger percentage if all those indirectly employed are considered Almost every person, young and old, has benefited to a greater or lesser degree through faster, safer, more comfortable transportation

Much has been written about modern research methods, but most of it remains incomprehensible to the average layman. When John Q Public makes what he imagines is a fuel economy test, he tries out three or four brands of gasoline and, on the basis of the most casual

driving, decides that one is better than the others of Courtes, such a "test" has no scientific basis. When research men tacked the problem, they climinate or take into account every variable, such as the air pressure and diameter of each tire, humdily, temperature, and barometer readings for the day, the condition of the road; the velocity and angle of the wind, and the manner of arceleration and deceleration.

Even one variable, the manner of driving, can make as much as 100 percent difference in miles per gallon. In a recent experiment in Detroit, two cars of

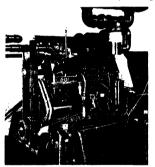

Research in Motor Industry . . . Co-operation and Exchange of Ideas, Findings . . . Has Resulted In Numerous Significant Developments

By J. J. FREY

Engineer in Charge of Technical Sales Division

Ethyl Engineering Laboratory, Detroit

the same make and model, both just off the production line, were driven in city traffic over the same route. One driver was told to "step on it" at green lightand to drive as fast as the law allowed until he had to put on his brakes for the next stop light. The other was told to accelerate and decelerate gradually, to

After this laboratory test of an engine, on which is mounted a V-belt driven supercharger, the engine will be installed in a truck for extensive road tests

sible The first car used twice as much gasoline as the second in covering the same distance!

Let us look, then, as an example, at how one group of research engineers made a fuel economy test. First, they searched for an absolutely level place where they could run cars at steady speeds and at pre-determined varying speeds without interference. This they found in the middle of the Mojave Desert in California—the table-flat bed of a dry lake. Next they devised an instrument which would measure and record the velocity and direction of the

wind at all times, a fifth wheel, which would overcome the variable of tire slippage, was installed and attached to a recording device to show exactly the distance traveled over land as compared with the distance traveled through air, asmeasured by an anemometer. Fuel wasfed into the carbureter through graduated gages which measured the sasolinact gages which measured the sasolin-

on cubic centimeters. Hamidity and temperature records were calculated at all times. The tests were run over and over in order to average the errors which the engineers knew would still creep into the calculations. Altogether, the work covered a period of months and cost several thousand dollars.

OU may well ask who went Y OU may well and to all this trouble and what did it prove The answer goes to the very heart and spirit of the group which furnishes the vehicles, the tires, the gasolines, the parts and accessories, right down to the last gadget used in motor transportation Fuel economy is the concern of many groups and literally hundreds of companies. The company which made this economy test manife factures tetraethyl lead, which is used by oil companies to im prove anti-knock quality of their gasolines. But the data

obtained were of interest to dozens of companies, showing, as they did, pertinent figures for what engineers call optimum compression ratios, carbureter settings and fuel anti-knock requirements of particular types of engines.

Although several companies often take part in one co-operative research program, I must, for obvious reasons, confine examples to the part of such projects about which I have personal knowledge and which concern, as above, the research activities of a company that manufactures anti-knock compounds for gasoline.

Some of the most interesting, and at

times, most difficult parts of research projects are the development of devores for making accurate tests and the development of instruments to measure pertinent variables. No laboratory can function without instruments and, strange as it may seem, very few of the important ones required can be purchased. When such instruments are needed, there is susually only one way to solve the problem—invent them. A few examples will suffice to show thy.

In one of our research projects, we wished to measure the air-fuel ratio in each of the individual cylinders of an engine. No instrument for such measurement existed, or if it did, we could not find it. So our engineers devised a set-up which enabled us to trap a sample of the combustion products of each cylinder and analyze them. In the same project we wished to find out the exact instant when each cylinder fired. The instrument finally worked out recorded the ignition timing on cinema film Sometimes a research project becomes so involved that the engine being studied is converted, for all intents and purposes. into an "instrument." Such an "instrument" looks like an ordinary heavy-duty truck until you get into the cab or lift the hood. The average truck driver would find gages, dials and gadgets he had never seen before Under the bood he would find that each set of three cylinders had its own fuel system, and many other modifications This "instrument" took several months to assemble and build and cost over \$10,000, but it proved immensely valuable in tests where it was necessary to eliminate the variables that always must occur when the performance of one truck engine is compared with another

WITH proper instruments, technically able and intelligently farsighted research workers, given sufficient time and resources, accomplish feats that in the aggregate become gigantic For example, 15 years ago, the engine of the average American automobile had a displacement of 252 cubic inches and could develop 59 horsepower. The average 1940 automobile engine has a displacement of 255 cubic inches. almost identical with the engine of 15 years ago, but it can develop 106 horsepower. Thus we see that in the short space of time that anti-knock compounds for gasoline have been available, the horsepower developed by the average American automobile has been increased over 80 percent, while its weight has remained approximately the same. A large part of the increase in power has been gained by increasing the pressure on the gasoline vapor in the cylinders before it is burned, which, in effect, squeezes more power out of each drop of gasoline. This is where the anti-knock quality of gasoline becomes important, for higher

Cathode-ray oscillograph for testing ignition system characteristics, and apparatus to determine spark plug insulator resistance and minimum firing current

anti-knock quality is required if gasoline is to burn smoothly under the stress of great heat and pressure inside a cylin

Seems to be a simple matter, doesn't it? Use gasoline of higher anti-knock quality, squeeze it a little tighter in the combustion chamber by increasing the compression ratio and presto, you get more power and better economy Unfor tunately, it was not as easy as that A multitude of problems had to be solved before this happy result was achieved It is more or less a truism in research that when a change is introduced to solve one problem five or six other problems may be created. That was what hap pened when compression ratios were moved up Research and expenience showed that the compression ratio which may be used with a given fuel is influenced by many variables including engine design, cylinder size, materials of construction, carbonization rusting and liming engine speed, tacket temperature, mixture ratio, mixture tem perature, volumetric efficiency and ignation timing

Engineers spent years studying these variables as well as the relation of compression ratio to bearing pressures valves, spark plugs, and so on Hundreds of tests were run on high, nedium, and low compression engines, both in the laboratory and on the road. Literally thousands of adjustments and re-adjust ments were made

Mells work eventually led to the universal utilization of higher compression pressures and higher compression pressures and higher compression ratios in passenger car engines. The average compression pressure in the 1931 automobile was between 90 and 100 pounds per square inch. Today the average is between 140 and 150 pounds Average compression ratio in passenger automobiles in 1925 was 4.5 to 1. By 1931 the average had risen to 5.25 to 1

Today at is 6.28 to 1 Optional compression ratios run considerably higher One manufacturer has available a cylinder bond giving 7.45 to 1 ratio. And teats have been run in the laboratory on engres with compression ratios as high as 11 to 1. The net result, as pointed out allow, task been more power and better eccesionly with very little increase in engree weight—burrefly, a better automobile for your money and the promise of a still better one in the future on the future on the future on the future.

B UT such results would not have been possible had not the oil companies kept in step with the march of progress by improving the anticknock quality of gasolines year after year. B there cracking processes, polymerization, selection of crudes, blending, and the addition of crudes, blending, and the addition of crudes, blending, and the addition of crudes between the property of traterily lead have provided the fine fack at low cost which have justified car manufacturers in designing popular-prized cars which reach ever higher plateaus in engine efficiency.

And this parade of progress has not stopped Supercharging for the average car may be the next step which automotive engineers take to squeeze more power out of better gasolines, and so our research workers for the past several years have been experimenting with the possibilities and problems of supercharging. In one test, a stock eightdoubled its power output after being cylinder passenger car engine almost supercharged The engine had an orig inal compression ratio of approximately 51/2 to 1 and developed 82 horsepower at 4000 r.p m. using fuel with an anti-knock quality of 78 octane number. After it was supercharged with an intake manifold pressure equal to 10 inches of mercury, it developed 160 horsepower, using gasoline with an anti-knock quality of 90 octane number. To carry this test further and to determine what advantage supercharging could give to this

Car with anemometer and fifth wheel speedometer. The former determines wind direction, velocity; the latter gives an accurate speed reading. At right Instruments within the car for use in conjunction with those shown above

engine without requiring a fuel of greater octain number than that oug-inally used, the compression ratio was lowered to 4.25 to 1. Using 78 octains fuel again, but supercharged to 10 inches of mercury, the engine developed 63 percent more horsepower than it had with the higher compression ratio on the same fuel.

Thus supercharging, which simply means forcing more an and fuel vapor into the engine by putting greater-than atmospheric pressure on the intake mani fold, seems to promise more of the same kind of improvement that was effected by increasing compression ratios But there are still a number of problems for research workers to solve before all of the hoped-for gains in efficiency can be realized. For example, in the tests in our laboratories we could put any pressure we wished on the intake manifold at any speed because the engine was on a stationary mounting, taking its air from a tank where constant pressure could be maintained The problem of achieving equal control with a blower driven by the engine being supercharged is quite another matter. Other laboratories in the research departments of automobile companies, and manufacturers of superchargers, are working on this problem now We are co-operating with them. giving them the results of our work and they giving us the results of theirs

But what will be the effect of such great increases in power on other patts of the engine? Will present engine steels, stand the gaff? Take value steels, for example. Fifteen year- ago, cast 100 was used for exhaust valve heads in main engines increasing the engine's output through increases in compression presure and more revolutions per minute made it obsolete. Sitherome steel became made it obsolete. Sitherome steel became the standard. Today, with still further demands, Stellite-faced valves have come to prominence, and with all the heat and pressure of modern high-speed operation they will open and close (and make a tight seal) 10 to 20 times a second for hours on end while you buzz merrily along without ever a thought of 1.300.000 jobs each valve is assigned to do in your engine every thousand miles.

What about spark pluge? Will supercharged engines call for still further improvements here? A spark plug that wasatisfactory in the car of 1925 would not last 15 minutes in a 1940 car rinning at wide open throttle Years of experimentation and testing have given the answer to the question of how to make them satisfactory for today's car. What about tomorrow? Only research, trial and error, and trial again can supply the answer

WITH this past experience in mind, it is easier to understand why super-charging is today of interest to many companies and many research workers and with they swap knowledge and conserve time and money by co-peraftive work. When you start changing the character of America's gasoline ragime, or start changing the character of its gasoline, you interest everyone in a group of industries employing literally billions of dollars.

Even when the finished product is in the hands of the ultimate consumer. many organizations in the vast automotive transport group lend a willing hand in solving problems in operation that may arise. A typical example with which I am familiar was a bad case of what the trade calls "tail pipe halitosis" experi enced by a large city bus company. The situation reached a climax in November, 1936, when civic organizations de scended on the company and demanded that something be done to stop the fumes of acrid smoke pouring from the exhaust One of our service engineers, a veteran of innumerable tussles with bus and truck problems, offered his services. The bus company furnished him an engine of the same model used in the buses and it was set up in our Detroit laboratory. After several weeks of experiments and tests, he worked out a procedure for correcting the trouble approximation of the presented it to the bus company. The officials tried it out on ten buses, found that it worked and eventually changed over their entire fleet. His recommendations—increased intake manifold temperatures, changes in carbureter characteristics, notuding learner tile mix-

tures—have been adopted by other bus companies and today are standard practice in meeting the condition known as "tail pipe halitosis"

Another field in which the continuing efforts of research have led to tangible results is power farming. Five years ago, all tractors were equipped with "compromise" engines-that is, they were designed with low-compression motors to burn kerosene, distillate, or gasoline But farmers who burned gasoline in their tractors got only part of the potential power in the fuel. Why not build tractors with high compression, automobile-type engines capable of using gasoline efficiently. This would give the farmer something he wanted. Tractor engineers who held this belief found ready assistance in our engineering laboratories. The advantages of high-compression tractors were determined by the laboratories and explained to the farmers and tractor dealers. Today nearly all tractor manufacturers make high-compression tractors.

As the new 1940 cars go on the market there are improvements and refinements not available on cars of previous years These changes represent a cumulative total of thousands of hours of research labor in a hundred different laboratories.

The same impelling force and relentless research which have given us today's engines and vehicles will push on to discover and utilize better principles and materials for the motor transportation of the future.

OUR POINT OF VIEW

No Vigilantes

TIMES of national stress alwaysbring with them curious and of mandangerous personal reactions. Mass hysteria, fostered by ill-founded rumors and frequently by malicious gossup, was the cause of many a viccous outburst during World War I. Spy sares set neighbor against neighbor, created suspicons that often had no more foundation in fact than a foreign-sounding name.

With present unsettled conditions pointing toward a future that cannot be predicted, it is comforting to know that our national security has been placed in the capable hands of the Federal Bureau of Investigation This organization, with the co-operation of all alwenforcing agencies throughout the nation, should certainly be able to cope quickly and reflectively with internal affairs that might have diseastions effects of permitted to get out of hand.

Speaking of this latest job of the F. B L. Director J. Edgar Hoover recently sounded a warning that, heeded, will assist greatly in keeping the United States on a level keel during troubloutimes "In the wave of patriotism that is rising in the country," said Mr Hoover, "there lies the danger of overrealous groups or individuals engaging in acts which are distinctly un-American in method, no matter how patriotic in aim. We need no vigilantes in this situation The vigilante method is disunctly contrary to American ideals of justice. The Federal Bureau of Investigation has been called upon to investigate all matters relating to espionage, sabotage, and violations of the Neutrality Regulations. In turn, the Federal Bureau of Investigation has requested co-operation of all law enforcement officers in the United States.

"This combined attack by Federal and State forces should be sufficient so far as investigation and prosecution are concerned," Mr. Hoover continued. "Beyond the efforts of these law enforcement agencies there is a need, of course, for the individual co-operation of all sincere and earnest Americans. This co-operation should be limited, however, to passing on to the proper officials all questionable facts or rumors which may come one's way. An alert public is the best defense against traitorous or inimical conduct. Let us be realistic and practical . . . but always calm in our judgment between the real and unreal."

Thus each individual citizen is squarely faced with his own share of the problem of controlling traitorous acts, yet adequately warned against actions that might not only hamper the whoels of justice but even render them momentarily ineffective —A. P. P.

Modern Pioneers

NOT so many years ago this nation celebrated 150 years of existence by the Sesqui-Centennial Exposition Next year it would be fitting if we should have another sesqui-centennial celebration, one that would mark one of the few extremely significant milestones in our history the founding of the American patent system. Our progress has been keved largely to that system and the incentive which it has given to individuals to originate, develop, and improve those brain-children that have made this country the greatest industrial nation on earth. Had it not been for the granting of patents and the profits therefrom our people would not now have the most advanced civilization ever known, nor enjoy the greatest number of conveniences, comforts, and luxuries, we would labor longer hours and have much less lessure time. Our patent system has been, indeed an important stimulus to invention, research, and in dustrial progress

It was with the thought that the American people should understand clearly the dependence of the nation on a sound natent system one that is not being changed constantly at the whim of would-be economists, reformers and malcontents-that this important anni versary is to be observed in 1940. The Modern Pioneers plan to mark the year by several interesting programs, the principal one of which will be the presentation of a number of awards to outstanding inventors and research workers Manufacturers and responsible executives or members of trade associations and scientific and engineering organizations are being invited to enter nominees for these honors. (Entry blanks may be obtained from Modern Pioneers, 14 West 49th Street, New York Closing date: December 1, 1939 Local dinners will honor selected local Modern Pioneers, and some time in February a national dinner, broadcast over a national radio hook-up, will honor a number of the country's outstanding Modern Pioneers.

That the whole program will succeed in its purpose seems saured by consideration of the Award Committee. It is composed of: Karl T. Compton, of M.I.T., Chairman; Forest R. Moulton, of the A.A.A.S.; George B. Pegram. of Columbia University; John T. Tate of the University of Minnesota, Edward R. Weidlein, of Mellon Institute; and Frank C. Whitmore, of Pennsylvania State College

We wish the organization the great success it richly deserves —O D. M

Not Poison

"THEY who get spanked" might well have been the title of a brief item lost to the general reader by its inclusion on our Legal High-Lights page last month. It is her resurrected for the same non-legal reader because of its stat month.

It seems that the Federal Trade Comless of the transfer of transfer control to the manufacture of transfer to the injurious effects resulting from the use of adminium cooking uteralls, and has filed a complaint against the publisher of the transfer Tracks, charging that the deceives the public. To us this is a masteripace of understatement

This bare-faced campaign to instill an awful fear in the mind of the public has been going on for many years-not just from time to time. It has been fanatic Why no one knows It has been insidious, powerful in its effect It has offered such a specious brand of "proof" that food cooked m aluminum acts as a slow noison or causes cancer or both that believers have carried on the evil work by word of mouth. And the believers have not all been unintelligent, simply unwise. A cultured lady once told this writer of a trained nurse in a great city hospital (of all places!) who was suffering from a serious case of aluminum-cooking-utensal poisoning!

The fight against this foul campaign of feat has also gone on for years Scientific American has been in the thick of this fight, has patiently ex plained over and over that aluminum cooking utensils can have no injurious effects on those eating food cooken in them In unequivocal terms, this maga zine has branded rumors to the contrary as malicious and entirely without foundation. We repeat the accusation American Medical Association, Mellon Institute, Government bureaus, and others have all done their share of the fighting against the rumor, have done their utmost to scotch it. Yet even now. with the Federal Trade Commission lined up against the fanatics, some people will probably keep talking of the dangers of aluminum-cooked food. But then, they're probably born pessimists and think they have every ailment ever mentioned by Sister Sue and Grandpap and Aunt Het, anyway!-F. D. M.

WHAT'S INSIDE THE STARS?

THE recent Colloguium on Astrophysics, at Paris, under the auspices of the Foundation Singer-Polignac at which the writer had the good fortune to be present, will have a place in the memory of its participants something like that of the great international conference of the Solar Union at Bonn in 1913shining the more brightly by contrast with the tragic days which followed. Unlike the earlier meeting, this was a small affair with only 16 regular delegates. and a scant dozen of other invited guests; but it was truly international. Seven countries were represented among the delegates, counting by present residence

-France, Belgium, Denmark, Sweden. England, Canada, and the United States Counting by country of birth, four more are to be added.—Holland, Germany, Russia, and India — represented by astronomers of distinction, all of whom are now living in the United States!

The sessions—held in an excellent room provided by the Collège de France—gave much more tume for the consideration of individual topics than is practicable at the larger congresses. One, or at most, two of the invited papers were presented at a session; the speaker had 40 minutes or so to present his conclusions, and almost as much time was often spent in animated and profitable discussion.

The problem of language-always more or less difficult at a truly international gathering-was very successfully solved All the speakers found it easy to present their views either in English or French, and their remarks were translated into the other language, sentence by sentence, as they went along, by a very competent secretary After a few minutes' experience, this proved remarkably simple; and, though of course it took time, it did not interfere with the free flow of thought and expression, even in active discussion (and the discussions were active)-as many as ten members sometimes commenting on a single paper The scheme worked so well, indeed, that it may be commended in other cases where the language problem has to be met

The Colloquium confined itself to two subjects, more closely related than appears at first mention; namely, the novae and the white dwarfs. All the delegates spoke with authority in one or another part of this farily extensive field.

Lundmark discussed the parallaxes and absolute brightness of the novae; Stratton, the evolution of absorption bands in their spectra; Edlen, the idenMost of Our Present Knowledge of the Composition of the Stars Concerns Only their Atmospheres . . . Now the Analytical Boring Machine Digs Deeper

By HENRY NORRIS RUSSELL, Ph.D.

Chairman of the Department of Astronomy and Director of the Observatory at Princeton University Research Associate of the Moint Wilson Observatory of the Carnegie Institution of Washington

Infication of previously unknown lines and Mrs Gaposchkin a spectrophotometric study of the bright bands and continuous background

Beals considered the relations of novac to Wolf-Rayet stars, P Cygni stars, and stars with spectra like Alpha Cygni, and Caposchkin their relations to the SS Cygni variables

Swings spoke of the physical problems of the atmospheres of novae and similar stars, Strömgren of theories of their internal constitution, and Baade of the amazingly luminous supernovae

Turning from the hugest of the stars to the timest. Kuper described the who dwarfs and other abnormally faint stars, announcing the discovery of many mones and discussing their physical conditions, and both Eddington and Chandrasekhar discussed the internal structure of the white dwarfs, and their bearing on stellar evolution

O UR less technical readers may be asked to excuse this condensed list of papers. Every one of them contained things which can be presented in non-technical language, and are of general interest. To describe them all would fill many pages like these At present, it may be well to follow a long-established rule of these columns, and speak of work which has already been published, in part at least, in professional journals.

The question of the composition of the great internal mass of a star might be supposed to be inherently unansverable. The spectroscope gives us a wealth of information about the atmospheres of the stars, and has established convincing evidence that they are, in general, very similar among themselves in composition (though not in temperature or pressure) and much like the Earth, except for a vastly greater abundance of hydrogen and hebium

But the atmosphere of a star—which forms less than the outermost billionth part of its mass—may not be a fair sample of the whole. We can only "get deeper" (to use Eddington's phrase) by an "analytical boring machine." For an ordinary star, the process is in outline

The central temperature of a star depends on its mass and radius, on the average weight of one of the free par ticles in its interior (atoms, electrons, and so on) and on the "model" on which it is built -- that is, the way in which the density increases toward the center. The latter effect is found to be remarkably small-it takes an increase of density at the center to more than a hundred times the general average to get a central temperature twice that for a star of uniform density The average "molecular" weight is more important, for the temperature is proportional to it. At the center of a star the atoms are knocked all to pieces Hydrogen (weight 1) goes into two pieces (with an average weight of 1/2); helium, weight 4, into three (average 1 1/3); oxygen divides a weight of 16 among 9 pieces; iron one of 56 among 27 fragments (or under actual conditions a few less). For all sorts of atoms, except hydrogen and helium, the average weight of one of the dissociated particles comes out close to 2 (on the chemists' familiar scale); for helium it is two thirds as great as this and for hydrogen only a quarter

Hence, the more hydrogen there is inside a star of a given mass, size, and build, the cooler the star will be inside. The rate at which heat leaks out to the surface will be correspondingly smaller, and the star will shine less brightly Helum has a similar effect, but to a much smaller degree.

The analytical theory has been fully worked out—first by Eddington, and in more detail by Strömgren—and it is found that a star containing no hydrogen should be about 300 times as bright but containing about 80 percent of hydrogen by weight. (For almost pure hydrogen the true theoretical brightness rises again; but this does not concern us here.) The brightness of a star with a given hydrogen content can be calculated from pure theory—assuming a good average "model"—and it is found

that such stars as Sirius, Capella, and the Sun are all much fainter than calculated for no hydrogen. Theory and observation agree for a hydrogen content of about 35 percent for all three stars. (This is by weight; by number, the light hydrogen atoms form a large majority.)

Reasonable change in the assumed density-model might alter the calculated abundance of hydrogen by a few percent but would not greatly modify it.

Most of the stars for which the calculations can be made come out of about the same composition. There are a few exceptions For example, Zeta Herculis has very nearly the Sun's mass, twice its diameter, and four times its brightness—which indicates a hydrogen content of about 15 percent.

This method, applicable to ordinary stars, fails entirely for the white dwarfs. But, strangely enough, the hydrogen percentage in these can be found in an entirely different way. In a white dwarf the free electrons are degenerate—they are sammed together as closly as the fundamental quantum laws permit. Under these conditions, the pressure varies as the 5/3 power of the number of electrons per cubic centimeter. Given this law, and the average mass of matter per free electron, we can work out all the properties of the body, if we know the total mass, finding its radius, density and so on The actual white dwarfs heing visible, and therefore hot on the surface, cannot be entirely degenerate, but there are good reasons for concluding that they are actually bigger than this theoretical limit by only a small percentage.

NOW for the companion of Sirius— the most famous of the white dwarfs-observations have been made of the "Einstein shift" of the spectral lines predicted by the general theory of relativity. For any star, this shift is proportional to M/R (where M is the mass and R the radius). According to the theory just described, the shift, E, is given by the equation $E = C M^{4/3} m^{5/8}$ where m is the average mass per free electron, and C is a constant which can be accurately calculated. Now for a hydrogen stom m = 1, there being one proton per electron. For helium m = 2 (mass 4, 2) electrons) and for heavier atoms it is nearly the same. For a white dwarf star of a given mass, and composed entirely of hydrogen, the Einstein shift should be less than one third as great as for one made up exclusively of heavier atoms.

For the companion of Sirius, the observed shift is intermediate between the calculated values for these two cases, and indicates a hydrogen content of about 35 percent.

There is unfortunately no other white dwarf for which our present data permit a similar test. There is one (40 Eridani B) for which we know the mass, but the Einstein shift has not been measured, and estimates of the radius from the spectral type are precarious.

At this point a complication must be mentioned. The question, what equations are to be used for a degenerate gas when the velocities of the electrons become comparable with that of light, is still vigorously under debate. Sir Arthur Ed-

Atop the physics building at the University of Minnesota this 12-ton dome for a 10½-inch telescope is insulated against temperature changes by two-inch slabs of Celotex loid between T-section members

dington maintains that the same formula should be employed, almost all other physicists agree in adopting a different one. The discussion, which is intensely technical, leads to the very frontiers of fundamental theory, and neither party has yet convinced the other.

Fortunately for our present interests. Chandrasekhar, who has worked out the consequences of the alternative theory with great analytical skill, finds that it, too, when applied to the companion of Sirus, leads to a considerable abundance of hydrogen. This conclusion appears therefore to be independent of the theoretical controversy.

But, if there is still about as much hydrogen in Sirius B (the faint companion) as in Sirius A (bright) the astrophysical consequences are important.

According to Bethe's theory, the stars derive their energy by converting hydrogen into helium, and it is only after the hydrogen is almost absolutely exhausted that they have any chance of contracting into the white-dwarf state. The existence of a single white dwarf contain ing abundant hydrogen appears therefore to be a grave objection to the theory. Eddington has, however, suggested a

Eddington has, however, suggested a way out. In Bethe's theory hydrogen is turned into helium, not directly, but by the action of catalysts—carbon and nitrogen—which are regenerated at the end of the cycle, and so used over and over again.

Suppose, however, that in each eyele a small portion of the catalysts is used up. Then, though the process would be repeated many times, it could not continue mediantely. The catalysts might be used up before the hydrogen, the formation of helium, and the liberation of sub-atome energy, would substantially cease, and the star might shrink unto a white dwarf with a good deal of its hydrogen left—plenty of fuel, but nothing to hurn a with

Those who have followed our recent presentation of Bethe's theory, will realize that only a very small change in it is required. He concludes that the N18 nucleus may meet two fates N" + H' = $C^n + He^i$ and $N^n + H^i = O^n + hv$. In the first case, carbon is regenerated; in the second, the very stable nucleus of common oxygen is formed, while the energy by is liberated. Now neither of these reactions has yet been observed in the laboratory (at least, when the writer last had access to scientific literature) Bethe, from rather general considerations, concludes that the first is many thousands of times more likely to hanpen than the second-in which case a small amount of carbon would catalyze the transformation of a very large amount of hydrogen But, if the second reaction had a probability a few percent as great as the first, the carbon and nitrogen might be used up before the hydrogen

Until more is known, by observation or by the advance of nuclear theory, about these questions, the stellar problem must remain open.

One difficulty, however, vanishes. It was very hard to see how Strius B, which shines feebly and is working at a low rate, could have used up its hydrogen before Strius A, which is working far faster The present answer appears to be simple it hasn't

There are other possibilities. Eddingion calculates that, in the intermediate stage of contraction between an ordinary star and a white dwarf, a star would reach its greatest luminosity and its highest central temperature when it had shrunk to only about twice its final radius. Such a star would appear intensely blue-white, and have a central temperature of 150,000,000 degrees or more, and a very high density. Whether, under such extreme conditions, some of the heavier elements could be built up, is another problem for the nuclear physisist—Bordeaux, France, September 11.

Is Light Slowing Down?

THE third letter of the alphabet, c, is harmless enough in the normal course of things, but in the hands of scientists it has become a hook on which can be said to hang the whole of modern physical science. For scientists have chosen this little letter to represent one of the most important constants of the universe—the velocity of light.

In almost every fundamental physical equation, whether it be concerned with the structure of the atom or the rate of expansion of the universe, whether it deals with the energy of X rays or the mass of a rapidly moving body, the letter c will occur. Way back in the middle of the last century, James Clerk Maxwell showed by a brilliant puece of

mathematical analysis that all electromagnetic waves — X rays, ultra-riolet rays, infra-red rays, radio waves—world travel in a vacuum with the velocity of light, and that this velocity was equal to the ratio of an electric charge measured on the electromagnetic system of units to the value of the same charge measured on the electrostate system.

Near the beginning of the present century. Albert Einstein, in his theory of relativity, indicated that the velocity of light was the maximum possible velocity attainable in the universe, and that the velocity of light in a vacuum would be the same for all observers. This velocity was no mere ordinary physical constant. like the velocity of sound, the viscosity of water or the density of lead. It was a constant which it was imperative for science to determine with great accuracy. Römer, a Dane, had been the first to do this successfully. Previously, in the 17th Century, Galileo had tried to measure the velocity by means of distant observers who uncovered lanterns but, naturally, his method was far too crude for him to obtain any results. Romer used the diameter of the Earth's orbit round the Sun as the distance to be covered by the light, while the required signals were provided in the eclipse by the planet Jupiter of his satellites. Römer's method was only roughly accurate, and during the 19th Century Some Physicists Suspect that Changes Occur in the Velocity of Light . . . Difficult to Prove . . . On the Whole, the Ouestion Remains Wide Open

By DOUGLAS W. F. MAYER

mechanical methods were devised and scientists in all parts of the world spent years in making observations and obtaining as accurate results as possible.

Nearly all methods used were modifications of two basic methods-the Fizeau toothed wheel and the Foucault revolving mirror. In the former system, light is passed between two teeth of a rotating gear wheel and reflected back from a mirror at the distant end of the base-line. The observer adjusts the speed of the wheel so that, by the time the light has been reflected back, a tooth has moved round and cuts off the light. Knowing the length of the base-line, the speed of the wheel and the number of teeth on the circumference, the velocity of light can easily be calculated. In the second or revolving mirror method, light is reflected from a revolving mirror along the base-line to a distant reflector and back again to the revolving mirror. By the time it gets back, the mirror will have turned through a small angle This will cause the light to be deviated. By measuring the angle of deviation with a graduated eyepiece, and knowing the speed of rotation of the mirror and the length of the base-line, the velocity of light may again be easily calculated.

BY the beginning of the present century, a large number of results of similar tests had been published, and these gate the velocity of light with varying degrees of accuracy. These results were copied from the papers originally published, but often the copying was done inaccurately, and reappeared in textbooks and scientific journals. It was again copied inaccurately for later publications. Incidentally, these usually ignored the stated degree of accuracy (explained below) of the mitial result.

In 1927, therefore, M. E. J. Gheury, and de Bray, a London scientist, undertook of the praiseworthy task of looking up and summarizing all the original reports of the measurements of the velocity. He published a list of these, but pointed out how inaccurate a good many of them were, and how many of the investigators had failed to apply important corrections. A strong test of the accuracy of a

scientific experiment is for the observer to take a large number of readings, and to see whether these show any great deviation from the men. The observer then states his result as, let us say, 100-2. In this case, the value 2 is the "probable error" calculated from statistical theory, and the result implies that the measured quantity is probably 100, but that the method is only sufficiently accurate to indicate that it hes between 98 and 102.

After carefully studying the subject. de Bray came to the conclusion that, up to 1926, only seven really accurate determinations of the value of c had been made. He tabulated these as in Figure 1, in which the second column gives the basic principle of the method used, whether toothed wheel or revolving mirror, while the final column gives the determined value in kilometers per second, with the degree of accuracy.

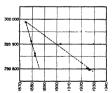

Figure 2: De Bray seeks explanation

De Bray was struck by the fact that here was a "constant" that was by no means constant, since its value seemed to vary from a maximum of 299,990 to a minimum of 299,796 kilometers per second-quite an important variation considering that c was supposed to be one of the fundamental constants of the universe. He accordingly decided to depict his results graphically, and obtained the series of dots shown in Figure 2. In this diagram the vertical scale represents the velocity of light in kilometers per second, and the horizontal scale the year in which the velocity was determined. Had the velocity of light been constant, the dots should all have lain in a horizontal line. Actually, they appeared to lie on two oblique lines, as shown in the diagram. De Bray pointed out that the three on the left had been measured over relatively short base lines, while the three on the right had been measured over longer bases. Cornu and Helmert's reading seemed to fit in with both groups.

De Bray reluctantly came to the conclusion that those measured over short bases were probably less accurate than

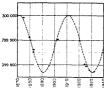

Figure 3 Edmonson's graph of 1934

those measured over long bases, and decaded, for the time being, to ignore these readings. The other four readings seemed to show clearly that light was steadily slowing down at the rate of just under 4 kilometers per second per year. De Bray suggested this tentatively to the world of science, then decaded to await further measurements.

In 1928. Karolus and Mittel-stack reported a determination of the velocity which gave a result of 299,778±20 kilometers per second and, in 1933, Peass and Pearson, continuing work Michelson had started at the Mt. Wilson Observatory, obtained a value of 299,774±11 kilometers per second This seemed to indicate clearly that the velocity of light was still decreasing, but the problem of the three "short-base" readings had yet to be solved.

Then, in May, 1934, Frank K. Edmondson, of Lowell Observatory, Arizona, suggested that the velocity of light on the decreasing steadily, but might be subject to a periodic fluctuation. He suggested that a period of 40 years, with a maximum valiation of 115 kilometers per second above and below a norm of 299,658 kilometers per second, might fit the facts. Represented mathematically, this gives the formula

c = 299,885 + Î15 sin 2π/40(T-1901) where c is the velocity of light and T the date of the year Represented graphically, the equation gives the simple "sine curre" shown in Figure 3. The nine dots on this diagram represent the nine accurate values then known, and the diagram shows how well they the suggested curve. At the same time, Edmondsop pointed out that his theory could not be properly proved until about

1938. If light were steadily decreasing in velocity, the value of c, in 1938, should be about 299,760 kilometers per second, while if the velocity were fluctuating, as he suggested, in 1938 it would be about 299,835 kilometers per second.

The idea that the velocity of light might fluctuate slightly was borne out by the experiments of Pease and Pearson. In 1929, Prof. Albert A Michelson, undoubtedly the world's champion timekeeper of light, worried by the fact that tmospheric irregularities (the astronmer's "bad seeing") interfered with is measurements, using long base-lines. mbarked on the heroic task of con tructing a mile-long vacuum tube. The ead-straight, air-tight metal tube, three cet in diameter, and evacuated to a ressure of 1/250 of an atmosphere, was ud down at the Irvine Ranch, Santa ina, California Measurements underaken by the United States Coast and eodetic Survey revealed that the tube as 5230 76509 feet long, while by wans of murous, the light was reflected ack and forth along the tube eight times, giving a base line of about eight miles. Three months after the tube was put into operation, on May 9th 1931 Professor Michelson died and the work was continued by Dr Francis G Pease. of Mt Wilson Observatory, and Fred Pearson, of Chicago University.

SERIES of 233 sets of measurements was made over a period of two years, the results being tabulated in Figure 4 The final result was stated to be 299.774±11 kilometers per second At the same time, it was stated that the readings showed two periodic fluctuations in the velocity of light. One fluctuation had a period of 1434 days, the other of one year In both cases the velocity varied by about 20 kilometers per second. The shorter period fluctuation nearly vanished during December 1932 and January 1933, reappearing in February 1933. It was suggested that this fluctuation might be due to some influence of the Moon, though how such an influence might work is not at all clear. Reluctant to believe that the actual velocity of light was changing, the observers also suggested that the variation might be due to instrumental changes, such as a possible change in the length of the light path, ground disturbances, errors in the timing mechanism, or a possible effect of refractive index in the path of light. Whatever their causes, the existence of these minor fluctuations gave a certain amount of justification to Edmondson's theory of a long-period variation

De Bray pointed out that the earth's magnetic field, which is known to fluctuate, might have some effect on the velocity of light. Accordingly, experiments were made to see whether the velocity underwent any change in a transverse magnetic field. The field used was 100,000 times more powerful than that of the earth, and the sensitive apparatus would have detected a change in velocity of one part in 20,000,000. No such change was detected. The suggestion that the refractive index of air might be changing was ruled out after referring to accurate determination this white made during the past 20 years

At the beginning of 1937, there came the news of another determination of c. made by Wilmer C Anderson in the Physics Research Laboratory of Harvard University The method he used was to subject a light-beam to highfrequency modulations by passing it through a Kerr cell The light beam was then divided into two portions by meanof a half-silvered mirror, and the two parts were sent over different optical paths. They were recombined and focused on a photo-electric cell difference in length of the two paths was adjusted until the photo-electric cell gave a minimum reading, indicating that the two halves of the beam were out of phase Knowing this path difference and the frequency of the modulation, the velocity of light was easily obtained

Between June 22 and December 5, 1936, 651 measurements were made, and showed no short period fluctuation which could not be attributed directly to physical sources. The mean result was 299,764±15 kilometers per second Later, in 1938, Dr. R. A. Houstoun of Glasgow University, Scotland, measured the velocity, using a piezo-electric crystal as an oscillator, and a base line only a few yards long. Initial tests gave a result of 299,760 kilometers per second.

These two determinations seemed to strike a death blow at Edmondson's fluctuation theory, so de Brsy, deciding

again to neglect the early short-base readings, advanced a formula c = 299,900 - 3855(T-1900)

to account for the diminution of c This gives a decrease in c of 3.855 kilometers per second per year, and produces a straight line on the graph, as shown in Figure 5, which also shows the readings now known — excluding, of

course, the three short-base readings So much for the experimental results. Meanwhile, what had the theoreticians been doing?

As was to be expected, the casting of doubt on something so fundamental as the velocity of light produced a veritable plague of theories, most of which were sooner or later proved either

to be untenable or to give a theoretical decrease in velocity of much less than 3 kilometers per second per year Most of the theories revolved around the supposed expansion of the universe. De Bray suggested that, if the universe were expanding, and if the ether were really material—a view still held by a few physicists—then the ether would gradually be decreasing in density, and the slowing down of light would follow as a matter of course. Calculations of the magnitude of such a decrease showed that it would be negligible compared with the decrease of 3.855 kilometers per second per year indicated by experiment. A similar theory was advanced by Edmondson, who suggested that doubling of the radius of the universe would cause the measured velocity to be halved. According to experimental results, however, the velocity of light should be halved in 60,000 years, where as the universe is believed to double itself only every 1,300,000,000 years. From relativity considerations, Tokio Takéuchi, a Japanese scientist, deduced that the velocity of light will be decreasing, due to the redistribution of matter and radiation throughout the universe, but, again, the calculated decrease was far smaller than that suggested by de Bray.

OTHER scientists have been bolder. They realize that the only real evidence for an expanding universe is the shifting of lines in the spectra of distant nebulae toward the red end of the spectrum-the "red shift". Assuming that the velocity of light is constant, the red shift is explainable only by the theory that the sources of the light-the nebulaeare apparently receding from the Earth with enormous velocities. It has been

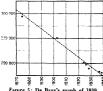

Figure 5: De Bray's graph of 1939

found that the velocity of recession is proportional to the distance away of the nebula, which gives rise to the picture of an expanding universe. The magnitude is such that nebulae at a distance of one megaparsec (3.26 million lightyears) are receding with a velocity of about 500 kilometers per second.

The bolder scientists point out that if the red shift can be accounted for by some other theory, then the nebulae need not be receding and the universe may not be expanding. Most of the theories advanced imply a change in the property of the light as it travels from the nebulae to the Earth, and several of these theories fit in with the idea of a decrease in the velocity of light.

One group of theories suggests that the energies of single packets of lightor "photons", as they are called-may gradually decrease during their journey through space, due to such causes as gravitational interaction, interaction with ionized gases which may exist in space, or simply by a gradual diminution of energy with time Such a diminution of energy would imply a diminution in frequency and, if the wavelength of the light were assumed constant, a diminution in velocity H J. Gramatzki has extended Maxwell's theory of light to allow for either a decrease of velocity with time of a change of dielectric constant with time. In both cases he showed that there would be a decrease in frequency (that is, a red shift), and also in velocity, but again the effect would be negligible compared with that of de Bray.

Zwicky has suggested that differences might be detected between properties of terrestrial light and light from distant nebulae. According to Pierre Salet, the velocity of light coming from stars is about 1 008 times greater than that of ordinary terrestrial light Zwicky has also suggested that the velocity of light may depend on its frequency, and that such a dependency would account for puzzling features about the spectra of certain novae Experimental tests, how-

ever, seem to refute this In turn, de Bray himself recently came forward with a suggestion that the frequency and velocity of light may decrease with time, and claims that observed red shifts can be explained by a decrease given by the equations

c = 299,774 - 173T

$$f = 762.2 - .4T$$

where è is the velocity in kilometers per second, f the frequency in mega-megacycles, and T the time in millions of This represents a decrease in velocity of only one six-thousandth of a kilometer per second per year-which, of course, is much less than de Bray's former suggestion of 3.855 kilometers per second per year to fit the observed measurements.

Meanwhile, other scientists hold that changes in the measured velocity of light have no connection whatever with the expansion of the universe, or with alterations of certain fundamental constants. They believe that the variation is due to some undetected phenomenon which influences the apparatus in some way or another. They stress the discrepancies between observations over short bases and over long bases, and also point out that the velocity of light can be meas-

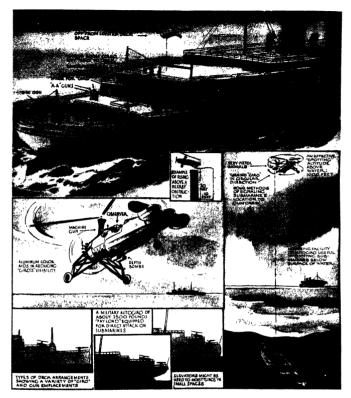

While the author of the ecompanying article, a young English physicist, does not anywhere state that a varying velocity of light has been proved, and that the remaining problem is to determine its amount, it is feared that an occasional hurried reader may run away with these beliefs. If questioned, many physicists might say something like this: "The chances are that there have been errors in some of the experiments, and that the velocity of light is a fixed constant. But, of course, we can't simply shut our eyes to the possibility that it is not fixed, even though this is more pleasant. This article will provide background for accounts of future experiments -The Editor.

ured indirectly, with compact electrical apparatus, by finding the ratio between the electromagnetic and electrostatic system of units. This has been done with great accuracy on several occasions, and the results show no marked variation, the value of c in each case being close on 299,781 kilometers per second.

Other observers claim that, if light were slowing down or its frequency altering, such alterations could easily be detected by sensitive interferometers All such experiments to detect any alteration have given negative results.

What could possibly cause the variation in the measured velocity of light other than fundamental changes? The answer is nobody knows Apparatus more sensitive than that already used will have to be designed and constructed in order to investigate the matter De Bray has stressed the point that, in the case of the revolving mirror method. it is assumed that the laws of reflection of stationary mirrors still hold good, and that the laws of reflection of a pencil of light, from a real or virtual source which may have a transverse velocity approaching that of light, are assumed to be the same as if the source were at rest. These assumptions, he suggests, may ultimately be shown to be inaccurate.

AT present, however, science stands at the crossroads. Experimental observations, on which the whole of science is said to rest, have presented it with a problem. Some changes have been detected in the measured velocity of light. One road leads to the type of solution involving extremely fundamental changes, the other to the theory that some new type of correction must be sought and applied. Both roads lead into unexplored territory. Which road will science follow? We can only watch and wait for the traffic lights to change.

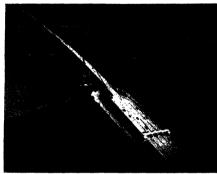

Ships Can Carry Autogiros to Spot Submarines

MERCHANT resuels need to be warned of the proximity of submarines if they are to elude or successfully fight them. Submarines can be apotted most effectively from the sir, but ships cannot carry ordinary planes (plus catapuths) and cannot stop, once a submarine is sighted, to host a plane aboard after its water landing. Use of warships to convey liberer or freighters subtracts striking power from the fleets

The autogiro, carried on individual ships and taking off from cleared present decks or built up ones, would largely solve this problem, believe Scientific American editors. The idea, conceived in our offices over two years ago by F. D. McHugh, has been called eminently practical by experts. Much experimentation is necessary, of course, but the 'gio has possibilities, as shown in our drawing. It can "jump off." 20 feet straight up and swing hard over to clear ships' super-structures. It can land with a run of about 10 feet, It can hover. It can carry machine guns to drive a submarine's gun c'rew below decks, and depth bombs to drop accurately while it hovers over the dark blob of a submerged submarine. To the ship's gun crew, it can signal a sub's location and spot shell splashes by flares, Véry pistol shots, or acrobatics. Finally, the autogiro can constantly patrol many miles around its mother ship.

DEEP PIERS BUILT IN STIFF TIDES

As the new bridge will look when completed. Note "lookout point"

New Suspension Bridge Near Tacoma... Two Deep-Water Piers... Enormous Tidal Current Pressure Forces Unique Anchored Caisson Construction

By CHARLES F. A. MANN

Outstanding of all the large bridge projects under way as a result of the past year's Federal RFC-PWA program, is the Tacoma Narrows suspension bridge across the narrow channel lying on the westerly side of the Tacoma Peninsula, Tacoma, Washinaton.

washington. Two features of this bridge are of particular interest to engineers. One is the fact that its central span of 2000 feet is the third largest auch span in the world, only those of the George Washington Bridge in New York and the Golden Gate Bridge in San Francisco being longer. The other is the manner in which the engineers solved the problems of the problems of the same of the problems of the same of the problems of the same of the sa

For more than 20 years, local people have dreamed of a huge suspension bridge across the Narrows to replace the ferries. Always two factors stymied the idea. One was the extreme depth of the

tidal current, the velocity of which, changing every six hours, reaches nearly nine knots. The second was the costliness of such a span in view of the semi-pioneer status of the section it would serve—a vast area larger than Switzerland, Holland, and Belgium combined.

A number of things brought the idea into a more favorable economic position in 1937. They were: the opening of the Olympic wonderland to tourists; the rapid growth of the pulp and paper industry; and the migration of hundreds of settlers from the midwest dustbowl to these cheap, well-watered landsall insuring greater travel. There was also the fact that the great Bremerton Navy Yard is rapidly becoming one of Uncle Sam's greatest naval bases, indicating a need for good highways and a fast Narrows crossing. Thus it was felt that a Federally supported project could easily liquidate about \$4,500,000 of its cost in 40 years.

The chief task confronting the builders was that of sinking the caissons and constructing the piers. The east pier of the Tacoma structure went down 200 feet below water level and the west pier 175 feet, as contrasted to the deeper pier of the two at the Golden Gate Bridge, which went down only 100 feet. Hence it was decided to employ open-well type caussons with a wooden form built around the first part of each caisson to permit floating it into position and lining it up before it was lowered to the bottom. The two main caissons were 118 feet 11 inches long, and 65 feet 11 inches wide, with boat-bow points. These two unus were fabricated in Seattle and towed through the Lake Washington Ship Canal to the bridge site in Tacoma

AFTER the sites for the two piers were located in the Narrows, 24 concrete anchor blocks, each weighing 600 tons, were dumped in a huge double errelearound each pres site. These blocks were later anchored by cables to the floating steel cassions to hold them in place against the terrific tidal strain. The blocks were cast on huge barges and were corrugated in such a way that they could grip the bottom mud.

Having provided the anchorage, the two floating steel skeleton forms, which were covered with heavy timbering with caulked seams, were towed into place and anchored to the blocks by cable. These floating caisson sections were spotted accurately by the use of shortwave radio and transits with telescopic sites.

The caissons were partitioned into 24

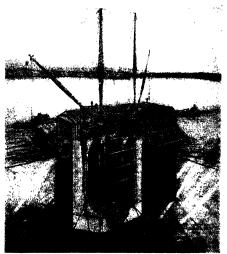

One of the monster 600-ton concrete anchors, sharply corrugated, that were cast on barges

feet 10 inches by 13 feet, all open at the bottom. Concrete was poured into the dividing walls of these sections to form a series of concrete and steel cells. As the added weight lowered the caissons a predetermined distance in the water, the anchor cables were adjusted to take up the slack, and the forms were raised so that another course of concrete might be poured. This was repeated over and over until the lower edge of the caussons struck bottom Clam-shell buckets then excavated through these cells until the entire caussons dropped through the muck to hard gravel. Concrete plugs were then poured at both the top and the bottom, leaving the cells permanently flooded with salt water.

The Tacoma structure has a total length of 5939 feet. Towers cover an area 19 by 63 feet at the bottom and 13 by 52 feet at the top, and carry two cables 17½ mehes in diameter. Each tower weighs 1875 tons and the two cables 3817 tons. Each cable anchoring

An "anchor" makes a big splash when dumped overboard from a construction barge at a pier site

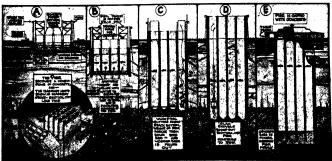

A caisson sinks lower in the water but is held rigidly by the anchors

consists of a steel and concrete mass of 25,000 cubic vards weighing 52,000 tons, lodged in the hillsides above the Narrows Each anchorage will form part of the main roadway. The bridge will have a 26-foot loadway and two five-foot sidewalks

The structure, which will be com-

pleted July 1, 1940, will reduce travel time from mainland to pennisula from 40 minutes to 10 and will be the best lighted structure of its kind. Towers and cables will be outlined in lights and the roadway equipped with sodiumvapor fog lights Airplane beacons will be mounted atop the towers.

Step by step, a pier is constructed. Slack in anchor cables is taken up as caisson sinks lower

Answer, Echo. Answer

E CHO, according to the Greek myth, was a nymph who pined away for love till only her votoe remained. This charming legend makes pleasant folklore, but the science of sonics has given the echo a much firmer basis Although echoes still possess as poetic, eerie quality, we can now explain how they magnify sound, return some vioces and ignore others, convert discords into music, carry whispers over long distances, and perform other weird feats which challenge the inagination.

Echoes are sometimes the radio stations of nature; without wires or sending-apparatus, they "step up" sound vibrations and hurl them enormous distances. Some years ago, 28 tons of dyna-

mute exploded in an Alpine ratiroad tunnel The terrific blast was heard by Swiss peasants 20 miles away, the apparent limit of the sound. Villages some 25 or 30 miles farther off heard nothing. Then, extraordinary news popped up 100 miles to the north, across the border in Germany, the noise of the explosion had been distinctly audible Had the sound of the blast "jumped" over a region 80 miles wide?

"Yes," said the Swiss Meteorological Institute. What had been heard in Germany was not the direct noise of the explosion, but an echo of it Every echo is.

you know, "mirrored" or reflected sound in this case sound waves, concentrated by the tunnel in which the explosion took place, had traveled upward, reached a heavy cloud formation perhaps 50 miles to the north, which amplified and then reflected the waves to points more than 100 miles from their original source.

Everyone knows that curved or angled mirrors can play curious tricks with an image Sound-mirrors (another name for echoes) act similarly they "bounce" sound waves from surface to surface. often altering their volume, pitch, and number of repetitions. Probably no echo has ever achieved the record described by Mark Twain- "you could utter a word and it would talk back at you for 15 minutes" But there is an echo in Oxfordshire, England, which repeats a pistol shot across a valley as many as 20 times the sound shuttling back and forth between two hills. Like some actors, this echo gives its best performance at night. There are Echoes that Magnify Sound and Others that Change Harsh Discords to Harmony . . . Echoes that Analyze Sound . . Whispering Galleries

By ALBERT CARR

It has never been heard to score more than 17 repetitions by day, the differ ence is believed to be due to the more uniform temperature of the air at night

A unique multiple echo exists at the Menai suspension bridge, in Wales There, a hammer blow on the main pier is returned in a series of staccato reports from each of the crosslocams, all the way

SOUND

Reflected sound that is clear and definite is an echo

across the rivei—576 feet. To get an equivalent result with light, you would have to set up a long row of mirrors, equally spaced, and place an object in front of the row, at a wide angle Then, by standing in the right position, you could see an image of the object in each mirror all the way down the line.

Some echoes disdain mere numerical glovy and strive for a single brilliant algory and strive for a single brilliant performance. If, near a certain tombine on the Roman Campagna, you speak an entire hexameter verse, the echo will centre hexameter verse, the echo will controlled with until you have finished, and then repeat it after you. Likewise in the deserted city of Mandu, in Central India, there is a spot where you can utter a long, soils sentence, and have it voyage back presently to your ears, unbroken.

To produce one of these marathon echoes, the sound reflector must be so far away that you have time to speak for several seconds before the waves can make the journey to the reflecting surface and back again. Sound travels a mile in about five seconds; an echo which will repeat a five-second sentence therefore indicates a reflector half a mile away. Only extraordinarily clear acoustic conditions will permit the voice to carry so

far; hence the rarity of this type of echo.

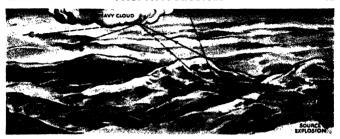

As some curved mirrors magnify your mage, some echoes magnify your voice.

Usually such "megaphone" echoes are heard in caves. At the famous quarried grotto known as the Ear of Dionysius, in Sicily, the crumpling of a piece of Cellophane will make you think a machine gun is at work. Why? Well, when echoes are thrown back simultaneously from many surfaces. their combined volume is louder than that of the original sound heard from a single direction. This phenomenon was once utilized by a troop of Mexican bandits when trapped by a superior force in a mountain pass Discovering that the crags around them multi-

plied both the volume and number of their voices, the handits tried desperate expedient. Yelling and shooting, they dashed for freedom. The echoes, resounding from all sides, made the enemy believe that a regiment was charging down on them; they fled and the little hand escaped. This story, long current south of the Rio Grande, has furnished at least one movie episode for Holly-

Mark Twain, veteran echo-fancier, claimed he knew an echo which would speak only German. We may smile at a the notion; but there are some echoes which are highly particular about the sounds they will do business with. One English echo has been called "The Suffragette," for, while it will respond to a woman's soprano voice, it pays no attention to a mair's.

This sex-conscious echo does to sound what a colored mirror does to light. In a polished red wase, for example, you will notice that the reflection of blue objects

Direct sound of a dynamite explosion in the Alps, as the author describes, was heard in the area up to point A, but not in the zone of silence from A to B. The echo from heavy clouds, however, was heard in the distant area from B to C

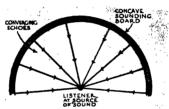

in it lose their color. The red light-rays of low frequency are reflected, while the high frequency blue rays are largely absorbed. The "selective" echo acts in the same way, throwing back some sound-waves in greater proportions than others.

The chief factors in this phenomenon according to authorities on somes, are the size of the sound reflector, and the variation in the wavelengths which compose a complex sound like that of the human voice Lord Rayleigh, the famed English physicist, showed that the intensity of sound scattered or reflected by an obstacle is

directly proportional to the size of the obstacle, and inversely proportional to the fourth power of the wavelength. (The same law, moderntally, applies to the scattering of light, and is used to explain the blueness of the sky)

When, according to this law, sound waves of various lengths traveling the same plane encounter a small obstacle, the longer waves tend to continue beyond it, much as large water waves pass around a rock and close in again on the other side, without substantial interruption The shorter sound waves, on the other hand, are scattered, somewhat like small water waves encountering the same rock. Consequently, when the sound reflector is small, the chances of the scattering and reflection of short sound waves are much better than those of long sound waves. Since the shorter waves represent the higher tones of sound, it is these tones which we hear most loudly when a small, distant reflector happens to produce an echo.

Certain selective or "harmonic" echoes have the curious trick of raising the pitch of sounds. At the Gap of Dunloe, in the lakes of Killarney, it is said that

How echoes are magnified The sound waves, having traveled out from the source in all directions, simultaneously coverge back on the shouter from all directions, causing more intense subration of the cardrum than was made by the original sound. He virtually shouts mouth against ear

the ghost of a long dead musician will accumpany shower plays a high there. It is perfectly true that the echo of each note comes back an octave higher, and that it provides a harmonous accompaniment for a simple bugle call. The principle is that of the selective echo, a small obstacle, such as a clump of trees, will return the first harmonic wavelengths, or octave, of a fundamental tone more efficiently than the tone itself.

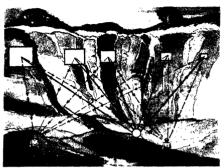

Everyone has observed how a prism or spectroscope grating breaks up sunlight into its component colors. Here and there an cho will do the same thing to sound, producing a "sound spectrum." At Bighorn Canyon, in southern Montana, the rushing roar of the river is sometimes echoed from a certain section of the cliffs in a howl like that of a police-car siren, beginning on a high note and sweeping down into the bass clef. Years ago Indians in the neighborhood used to shun the spot for fear of "evil spirits" Today we know that the various wavelengths in the sound of the river are reflected by different parts of the jagged cliff, reaching the ear separately, instead of all at once If the observer takes an

other position, he can cause the order of the sounds to be reversed, so that the echo begins with the deep tones, and rises to the treble Physicists say of echoes of this type that they "analyze" sound

bly beach, analyzed and echoed harmonically by the forest behind

The muscal echo is certainly the most claiming of all the numerous echo family Its principle seems to be to repays evil with good on Saddleback Mountain in Maine, the most hideous discords—such as an Indian war-whop—are returned as a delightful, soft, muscal note such as as a regenerally found only where there are symmetrical rows of the trees which "cut out" or abort certain sound frequencies, and reflect the others in a harmone relationship.

Perhaps the most dramatic of all echoes are those in which the sound is reflected from deeply curved surfaces. The whispering galleres of the world are all of this type One of the best known is under the great dome of St. Paul's Cathedral in London. There a whisper will creep across from one side of the dome to the other, to be picked up with astonishing distinctness on the opposite side, 102 feet away. The Ear of Dionysius, already mentioned, is one of the finest of all whispering galleries. At its top is a small passageway where the visitor can distinctly hear the breathing

An abstract diagram of the action of an "analyzing" echo. Large reflecting areas throw back more of the deeper sounds; small ones more of higher sounds. Owing to differing total path lengths these "analyzed" echoes arrive in succession, but from high to low for one listener, low to high for the other

of a man on the floor, 120 feet below. The tyrant, Dionysius of Syracuse, conceived the notion of imprisoning political enemies in the Ear, and by listening at the top, was able to overhear their whispered plots and secrets

How is it that a whisper which cannot be herard for 20 feet under normal conditions will carry 30 times as far in a whispering gallery? The explanation hes in the fact that the sound is "Sainted" off the smooth inner surface of the round dome again and again, traveling in a series of ares A helpful analogy is to magnic a billiard ball with "forward spin" as it strikes a cushion at an acute angle Under the right conditions the ball instead of being slowed down, pineks up" Smilarly, the volume of sound "picks up" in whispering galleries as it travels over the curved reflector.

E CHOES have been used as a method of torture. In the Cave of the Snake. in the wrinkled and lonely hills of the Kaimui Range of India, the least sound is repeated in a low rushing murmur that seems to pervade the doomed chambet A torture-loving Raiah once conceived the notion of putting his victims, one at a time, in the pitch blackness of the cave with no company but that of a deadly black cobra. There was no way of telling how soon the cobra would encounter its destined victim and strike But every time it moved or bissed the slithering sound would seem to come from all directions. Under the unbearable suspense the prisoner would die a thousand deaths before the fatal moment came

However, the Rajah felt that in not overhearing the sufferer's to ture he was

missing the best part of the fun. So he had a small opening made in the sealed entrance. And—as was to be hoped—while he sat with his ear to this opening. the snake crawled up and by him.

The best known of America's whispering galleries is in the Capitol at Washington, in Statuary Hall, where if you stand in the proper spot you can communicate by whispers with a friend 50 feet away.

Most land echoes seem to have no other purpose than to entertain the curous. But at sea, echoes work for their lung, meaning orean-depth for navigators. The echo depth-finder used by the United States Coast and Geodens warvey in charing the bottom of the necean, and carried by particulally all important vessels, enables a shy running at full speed to obtain four seundings a second in depths of 600 feet, bound, be

it noted, travels approximately five times as fast in water as in air.

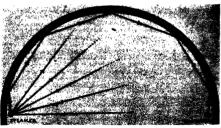

The principle of the instrument is simple enough. Sound waves, produced under water, speed to the ocean bottom, and are reflected upward. An electrical device measures the elapsed time between the transmission of the sound and the return of the echo, and this time interval is recorded in terms of depth. In war time these depth-infinders have helped ships to detect the presence of submarines by recording the sound wheth they make.

The story goes that many years ago, in the cathedral at Grigenti in Sicily, a gentleman was kneeling alone near the high altar, when he suddenly heard a distinct whisper have sinned. "Bless me, father, I have sinned."

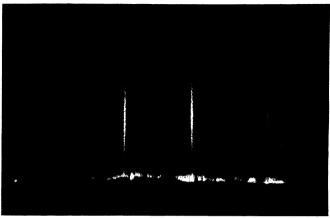

Startled, he looked around. There was no one near him. The whispered confession continued. Amazed, he concluded that it could only come from a confessional booth over 100 feet away. He approached the booth, but at once the whisper ceased. Returning to the original spot, however, he heard the words as clearly as if they were being mui mured into his ear.

Unfortunately, he was not content with the discovery of an acoustic phenomenon. Delighted at the prospect of rare entertainment, he invited some of his friends to join him near-widropping on the confessions of their neighbors. But, appropriately enough, in the very trist confession, he heard the sound of his own wife's voice admitting sins no husband cares to have on his wife's

A MONG rchoes as among people, there is infinite diversity. One finds not only easygoing, good-natured echoes, but grumblers, loud-mouthed bores, wisecrackers, show-ofs, temperamental artists, and a few hard workers, but Little Sir Echo always has one advantage over merely human sound-makers. No one expects him to be original

Sound creeps around the concave wall but soon becomes attenuated elsewhere

Spectacular pillar halos at Wilbur, Washington, photographed at 12:15 A. M. by S. B. Breed. Five-minute exposure at f/3.5

PILLAR HALOS

XCITEMENT Caused by Freakish Lights" was a headline in the Wilbur (Washington) Register. "Last Thursday night." the news item beneath it stated, "those of our citizens who were awake witnessed a display of freakish lighting effects that is seldom equalled for beauty. From every outdoor light-street lights, electric signs, and automobile headlights-there arose perpendicularly a shaft of light high Within these ghost-like into the air. beams there flickered and danced millions of particles of frost." On this occasion one Scientific American reader. S. B. Breed, of Wilbur, thought to photograph the odd phenomenon and sent this magazine the illustration shown above, with a request for a scientific explanation.

When readers send this magazine decriptions of odd meteorological or atmospheric phenomena for explanation, the editors turn to W. J. Humphreys' "Physics of the Air," a standard advanced reference work about this particular corner of science; often also, as un this case, to the author himself, Dr. Humphreys, because his lifetime work as Professor of Meteorological Physics at the United States Weather Bureau in Washington, has brought to his attention myridad of meteorological oddities. "The photograph," he replied, "is of pillar halos and is the best I have seen of that phenomenon Pillar halos," he ontinued, "are produced by reflection from the upper and under ades of tabular snow crystals, which tend to fall flatwase" In extension of his comments reference to the month of the professor Humphreys exted an article in the Month's Weather Resease of the United States Weather Bureau, by B W Currie, Professor of Physics at the University of Saskatchewan. Canada, describing a similar happening, and the following is quoted from that article.

"The color of the light from the pillars, and its state of polarization, show that they are caused by reflection. The color of each pillar is exactly the same as that of the light below it, the red pillars from neon electric signs are particularly noticeable. The apparent height of a pillar increases with the intensity of the light source. Calculations based on known distances to light sources and the measured sizes of the corresponding pillars on photographs often gue heights in excess of 1100 feet.

"Two kinds of crystals—thin hexagonal plates and thin broken fragments of snowflakes—cause the pillars. Only the first kind is found on calm nights when the most brilliant displays occur. Both kinds of crystals may be found when the pillars are seen on windy nights.

"Wind velocities less than eight miles per hour seem essential to the formation of bright pillars. If snow is falling, the pillars can be seen only if the wind is strong enough to break the snowlfakes Temperature conditions show no untornity, partly because the cryatals are formed at higher levels and then fall to the surface."

Sometimes pillar halos are similarly seen above the sun or, if the sun is high, below it as well.

Related directly to pillar halos are several phenomena which do not at all resemble them in shape: certain arcs and circles, seen surrounding the sun, often in elaborate complexes like schoolroom exercises in geometry. All have scientific names such as perhelic arcs and circles, anthelic arcs and heliac arcs. But the plot rapidly thickens, for a part of these are caused by reflection, and, to complicate the complexity, there is a third class of ring phenomena due to diffraction: coronas, solar or lunar. Halos are red inside, blue outside, coronas the reverse. Writers often confuse the three classes and who can blame them? Short of close study and perfect memory it is safest not to leave the vicinity of a textbook.

MONTHLY DIGEST

BIKE TIRES TESTED

Like its big brother, the automobile tire, the bicycle ture now undergoes actual road tests in addition to laboratory check-ups to insure serviceability.

ups to insure serviceability.

On a unique machine invented by engineers of the Fisk Tire Company, four bike tires can be tested at one time by means of a trailer arrangement hooked to the rear of an automobile.

The four tires run simultaneously, each under an individual load of 125 pounds. The

Heavily loaded tires under test automobile pulls them at 25 miles per hour,

automobile pulls them at 25 miles per hour, rain or shine, to simulate actual service conditions

According to A E Benson, Fisk product development manager, the tests provide the following information. Behavior of tire on following information and the following information of the following information in the following the

Indoor tests on another machine provide a double check on the same conditions

PERFECTED "RUBBER LUNG"

A SHORT time ago newspapers carried he story of the first use of an artificial lung on a mother during childbrith. The mother was afficted with paralysis a short time before the child was to be born and had been kept in an iron lung. Delivery was, of course, impossible while abe romained in this machine, so a smaller, newly

Conducted by F. D. McHUGH

of Aeronautics, New York University

developed lung was borrowed from the family of a paralysis patient, Fred Snite The delivery was successful

The small lung which served in this case was one which was discussed in Scientific American about two years ago, and was veloped in part by the General Tire and Rubber Company in an accompanying illustration will be seen the latest perfected model of this lung, which not only provide the pattern with a regular rhythratic supply of air but leaves the lumbs free for any necessity of the second of the second

This emergency lung, which is called the "General-Collins," is easily transportable, is operated by a ¼ horsepower motor or

by a hand pump if electricity is not available, and is so inexpensive that it might be carried as regular equipment in even the smallest hospitals, in police emergency squad cars, fire-fighting units, and by firstsial organizations of all kinds. It has been designed in four sizes to care for patients from infants to large adults

BACTERIA CAUSE KEROSENE EXPLOSION

BRITISII authorities have for months been puzzled by mysterious explosions in gasoline storage tanks holding their war time fuel Sabotage was suspected but un proved, for the terrific explosions brought complete catastrophe. Finally a kerosene tank blew up and, after the explosions bubbles of gas were noticed rising from the layer of water at the tank's bottom on which the kerosene had been floating

which the kerosene has been nousing. The government's expert on the generation of gases by bacteria, Dr. A. C. Thaysen, examined some of the water and sediment. It was found that they contained a new kind of bacteria which can live in kerosene and ferment it into 10 percent ethane and 90 percent methane. It was undoubtedly

these explosive gases, generated by the bac-teria, which caused the explosion. While Dr. Thaysen has not solved the puzzle of the gasoline explosions, he is virtually cer tain that a similar action was responsible Science Service

RLOOD

THE Japanese are said to have added to the soldier's name on his identification tag, which he wears around his neck, one of the letters: O, A, B, or AB. Precious time is thus saved if the soldier is wounded and needs a blood transfusion, for the letters indicate his blood type, previously determined

DE-ENAMELING LIGHT SHEETS

To its line of sand-blast guis, and an employed by makers model which is now being used by makers of vitreous enamel products, such as stoves, refrigerators, cabinets, and sinks, for de enameling defective sheets or parts which are ordinarily a total loss. This new gun has five outlet nozzles or orifices through which the sand is discharged with a brush like action, cleaning without peening or distorting sheets 19-gage and lighter. Be-

Sand blasting for reclamation

sides de-enameling, the makers recommend this type gun for cleaning wood, stone, and other materials, the surfaces of which might be damaged by a harsher, single nozzle

GAS-COOLED COMPRESSOR

THE world's most powerful air-conditioning compressor unit, with a cooling al to the melting of 100 tons ours, has just been announced use Electric & Manufacturing be immeriant feature of this wini la hor.

For defense against low-flying aircraft

all air-cooled and required much more space This new equipment, therefore, has 12 percent more efficiency and its space requirements have been reduced by two thirds of importance to theaters, restaurants, and the like, where space is at a pre-

100-MILE-AN-HOUR

ANTLAIRCRAFT COMBAT CAR

OUIPPED with three machine guns and a cannon, capable of traveling more than 100 miles per hour, built of .50-caliber bullet-proof armor plate and glass, mounted on bullet proof tires, able to climb grades of 50 percent inclination and travel through mud, sand, and broken ground, having a cruising range of 225 miles at 70 miles per hour, as easy to drive as a motor car -- that, in substance, is the newest type of anti-aircraft combat car.

This new mobile unit is a powerful arm of defense against low flying aircraft on ground strafing missions. Its armament, peed, maneuverability, and bullet-proof construction make it always ready for instant use

Designed by Preston Tucker of Tucker Manufacturing Company, this "tank" was made possible by use of the most modern steel construction process-are welding Arcwelded construction actually makes the machine bullet-proof. Welding does away with bolts and rivets which become worse than projectiles when driven into the tank by heavy gun fire. While eliminating this hazard, the arc welds are themselves bulletproof Welding on the Tucker Tank was done with electrodes and arc welders manufactured by The Lincoln Electric Company.

This tank is equipped with one 37mm full-automatic cannon firing at a rate of 120 shots per minute, and three .30-caliber machine guns. The turret rotates freely, giving complete firing range, and all glass is 2½ inches thick and so placed as to give full

A small of LLA rails an hour is possible

speed transmission. In addition, the unit has a 108-inch wheel base and a standard racing-car arrangement in springs and chassis. Tires are apparently sponge rubber "airless" type.

Radio equipment and compass are con tained in the interior which is air conditioned for comfort

TREES

MORE than 6 mill on trees were planted in windbreaks and shelterbelts last year in a total of

ERSATZ RURRER

W/ITH synthetic materials in many instances replacing more expensive and less satisfactory natural products, the question is often raised as to why substi tute rubber remains so high in price

Using the production of Buna, Germany's substitute rubber, as an example, Plastics (London) points out that the process is so complicated that certain basic costs cannot be decreased The works plant is costly, maintenance is much higher than in ordinary plants, the highly inflammable materials need special precautions, continu ous testing and research are expensive, but necessary, adjuncts But the main reason for high cost is the fact that there are so many intermediate processes The first step is the manufacture of car

bide from lime and coke in an electric furnace using 10,000 volts. This needs a sizable power station to produce the necessary 100 to 200 tons of carbide a day. The carbide is then treated with water to produce acetylene The acetylene is trans formed by catalysis and hydrogenation into the chemical butylene glycol. The yield of these two processes is only 35 percent of the theoretical. Two more steps, another or the theoretical. Iwo more steps, another transformation, and a polymerization, yield the rubber substitute. The polymerizing agent is metallic sodium, difficult to handle.

To make one ton of rubber, four tons

of acetylene are required. And to make this quantity of acetylene, at least ten tons of carbide are needed.

It is interesting to note that, should the cult of self-sufficiency die out, the production would decrease and the price would increase. And, as in the United States, the use of the synthetic material would be restricted to its proper and special uses based on its inherent advantages over the natural material.

AERO-BIOLOGY

HAY fever victims will find aviation an aid in their woes if the researches of "aero-biologist" C C. Durham, of the Abbott Laboratories, are successful. Dr. Durham is a botanist who investigates the distribution of pollen with the aid of a microscope and a kit of Vaseline-covered The slides are fitted into a "skyhook," and flight investigations of the upper atmosphere have been made with the aid of United Air Lines, Pan-American Airways, and Pennsylvania Central Airlines. Above 6000 feet there is little ragweed or other irritating pollen to be found. Even at ground levels in the Pacific Northwest the air is virtually free of any hay-fever-causing pollens. Flying in the Yankee Clipper, Dr. Durham's slides show no spores farther from land than 275 miles Sufferers from hav fever had better spend their lives flying, particularly flying over the Atlantic! - - A.K.

THE ASBOTH HELICOPTER

W/E have described at some length in these columns the remarkable characteristics of the Focke helicopter, which is of the type where airscrews, turning in contrary directions, are mounted on each side of the fuselage Now, thanks to the Aeroplane, (London) we are able to give a description of the latest Asboth design, which is apparently to be built in England. The Asboth machine, illustrated in the drawings, is known as the A H. X With a Gipsy engine of 200 horsepower, a gross weight of 2148 pounds, and a disposable load of 385 pounds, the A. H. X. is estimated as having the following performance Maximum horizontal speed, 107 miles per hour, ceiling, 11,500 feet; initial rate of climb, 1760 feet per minute, lift, 3260 pounds, giving an excess of lift over weight of 1100 pounds Speed of vertical descent

End view drawing of the Asboth helicopter. Wheels retract into wing

with the blades auto-rotating is somewhat high, in the neighborhood of 40 feet a second, although the vertical descent speed can be reduced to 16 feet a second by gliding the machine down like an airplane or an autogiro

The drawings give only a hint of actual construction Incidence of the blades is varied from hub to tip. If the engine fails, the incidence is automatically changed, so that auto-rotation follows. Without automatic auto-rotation, a helicopter would be a dangerous vehicle when the engine quits.

The blades are set rigidly on the hinge and do not flap. There is a "four function" hub. The hub allows the sincrews to be titted forward to give forward thrust, and permits auto-rotation as previously stated. Control surfaces are carried in the faired beam, which is really a small wing. The landing gear citracts into the wing, and

the now commonly accepted trucycle landing gear is embodied in the design. We admit that this is a sketchy description and hope that more details will shortly be forthcoming. In the present state of the art it bughly desirable that both the superimposed ansacrew type of helicopter and the outboard airscrew type should be developed in competition with one another —4. K.

THE FUTURE OF

DR H E WIMPERIS, former Director of Research of the British Air Min istry, is a man of vast experience in aeronautical matters. His recent address before the British Association for the Advancement of Science, on the future of flying, may therefore be regarded as an authoritative view of things to come

Speaking of materials, Dr Wimperspositions out the virtues of the high-strength aluminum alloys so generally employed to day in the building of aircraft. But aluminum alloy means hundreds of thousands of rivets in a large airplane. Therefore, plastic materials, while no better from a strength point of view, may mean real improvement in production methods.

What is the position regarding speed? Physiologically there is no limit to speed, provided only that high speed is not asso crated with rapid maneuver. Does not the earth spin around at vast speed without incommoding us in the least? But there are two probable limits to airplane speed For commercial aircraft this should be around 250 miles per hour, simply because it is uneconomical to fly faster. For mili tary aircraft the limit of speed is likely to be between 500 and 600 miles an hour, because of the "compressibility burble" which occurs near the speed of sound, and which even the best airfoils cannot postpone indefinitely With compressibility burble, the drag or air resistance increases enor

What of the engine? Three thousand horsepower in a single unit is in sight. One great improvement which has entered British but not American practice is the sleew-valve to replace the conventional popper valve. The alever-valve is no novelty (it has been used in the automobile) and it has only half the component parts of the ordinary popper valve, permits inlet and conductive the conductive property valve, permits inlet and conductive the conductive the conductive that the conducti

the cooling air to produce thrust. In such a case, instead of drag, the cooling system may actually produce forward thrust!

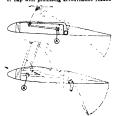

Special wings may be developed which will keep the flow over the surface of the airfoil laminar instead of turbulent, with marked improvement in performance. But then the position of the propeller must be changed. It is not the slightest use to design "laminar flow" wings if the slipstream of the propeller placed at the leading edge of the wing upsets the air flow. Wimperis therefore argues in favor of the pusher propeller, that is, one placed behind the wing. The pusher propeller introduces problems of its own, such as moving back of the engine and change in trim or balance of the aircraft; the necessity of a long shaft drive from the engine, with attendant vibration troubles; and proximity of the propeller slipstream to the tail surfaces Nevertheless, the combination of "laminar flow" wings with pusher propellers offers an attractive vista.

The higher the wing loading, the greater the speed and carrying capacity. The Wright brothers carried a loading of 1½ pounds per square foot of wing area. Dr Wimperis speaks of a stall speed of 100 miles per hour, and wing loadings of 40 pounds per square foot. Particularly intransilatinic flying we may expect tre mendous wing loadings to permit non-time the permit the pe

These semi-popular, semi-technical views of a well-informed man are helpful to both layman and technician —A K

PUSHING THE FLAP STILL FARTHER

THE flap has proved itself highly useful in airplane design, but aeronautical engineers are never satisfied. Therefore, double-flaps, designed by H B. Irving, are being tested in England. Our own N.A.C.A. is experimenting with a Venetian-blind type of flap with promising aerodynamic results

Two types of the Pidcock combination "slat" and flap for planes

to compensate for mechanical complexity. The Aeroplane (London) describes briefly the Pidcock combination of forward "slat" and flap illustrated in two of our drawings. In the Pidcock combination, the effect of the flap in increasing the lift capacity is combined with the lift increase effect of the slat which emerges from the surface of the

wing, and gives a biplane effect. The in-clination of the forward slat can be adjusted by the eccentric at the points A on the drawings. There is another reason why the combination of slat and flap is worth con-sidering: The depression of the flap tends to nose the airplane down; such a tendency would be counteracted by the lift force forward of the slat .-- A K.

CONTRAST IN TRAINING

PLANES

TWO of our photographs show a definite contrast in modern training planes. The Stearman PT-13A Army primary training plane is a biplane, powered with an engine of more than 200 horsepower, with a top speed of around 150 miles per hour. The Stearman is a rugged biplane, of short span, so that maneuverability is high and there is ruggedness available for the most violent stunting The cockpits are open so

The Porterfield Model 50 is a decided contrast It carries only a 50-horsepower Continental engine, of the four cylinder opposed type, and the open cockpit can be converted into a comfortable cabin with plenty of vision The Porterfield Trainer has been specially designed for the thousands of students who will undertake C. A A flight training all over the country The small ships now being used for such training-the Porterfield, Aeronca, and so on-arc remarkably economical, easily

ers across the North Atlantic straight from factories in Canada is much more practical In fact, the Allies may expect a great deal of help in aerial warfare from Canada. The Society of British Aircraft Constructors tells us in a news letter that 11 major Canadian engineering firms are handling aircraft production work, and that the pulse of production is quickening every week. The network of factories is spread throughout the Dominion, with torpedo planes being built as far west as Vancouver. Our northern neighbor has a great opportunity in military aviation _ 4 K

IS THE WESTWALL INVINCIBLE

TF Germany's bristling Westwall proves invincible to attack in the present war, it will be the first great wall in history that has ever completely justified the trust put in it, says Science Service

China's Great Wall, a barrier 1500 miles long, 15 to 30 feet high and reinforced by thousands of towers, was built to shut out barbarians who kept swooping down from the north (.osting thousands of Chinese lives in the construction, one flippant crack later summed up its worth "The Chinese never got over it but the Tartars did

Two modern training planes with destrable characteristics. Below The Porterfield Trainer, and, right, a Stearman primary trainer

handled, of slow landing speed due to their low wing loading (6.5 pounds per square foot on the Porterfield), and safe in students' hands.

Neither the operators who give the in struction nor the students who undertake it have any reason to complain of the equip-ment at their disposal. Main data on the pen ta their disposal. Penterfield Trainer are: High speed with open cockpit, 95 miles per hour; gross weight 1100 pounds; useful load 436 pounds; length 22 feet 6 inches; wing span, 34 feet 9 inches; wing area 168.8 square feet. The students for whom Uncle Sam is providing flying training are to be envied.—A. K.

CANADA TO THE RESCUE

THERE was a beautiful idea propounded in the press that British and French warplanes could fly to Poland's aid and shuttle back and forth, dropping deadly bombs on the German forces. The great distances involved and the destruction of the Polish aerodromes rendered the plan unfeasible. But the scheme of flying bomb-

Hadrian's Wall, which crossed Britain from coast to coast, fortified Roman Britain against invasion from tribes of the north Although the last word in 2nd Century A D. military construction, the strongly fortified harrier was stormed and broken during more than one conflict.

In Germany itself, Rome's old Limes Line that marked the limit of conquest was no particularly heavy, but the Romans thought it adequate when they had backed it by block-houses and manned it for defense. When internal troubles weakened the empire, however, Franks and other tribes ran over this great wall and swept on in triumph into Gaul

TRULY VERSATILE

A NUMBER of amazing products of rubber hydrochloride, in a form called Tensolite, were shown us recently by Henry D. Minich. Rubber hydrochloride has been known for a number of years and was introduced in a stabilized form by the Goodyear Tire and Rubber Company in 1934 under the now well-known name Pliofilm. Mr Minich began working with this product and developed a machine with which he does things to it. From Pliofilm, treated and turned into Tensolite, is made a dental floss, bristles of many kinds, tape in numerous colors, and, even a fiber as fine as cocoon silk. One of the bristles has an abrasive core, so that when made into brushes it will abrade a surface at the same time that it polishes. Sheets have been made that are, in the commercial grade, .0002 of an inch thick, but experimentally they have been made to a thickness of 00008 of an inch. This last sheet puts the word "gossamer" to shame, for it actually floats in air.

Tencolita laminations in different colors are made into attractive striped tapes. Endless belts may be made from it; or colorful sheets for such things as raincoats, each side of a different color. Air-like filaments have made very satisfactory fishing lines and lead-

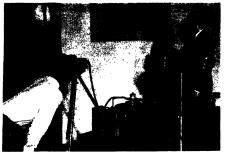

ers, badminton and tennis racket strings yarns and threads and tapes have been woven into cloth, belts, trimmings, and haskets

All Tensolite products are proof against water, oil, grease, acid, alkali, perspiration, mold, and vermin. They stand all normal temperatures, are non-explosive, and can be printed. They have long shelf life be printed and may be cleaned with some and water or may be dry cleaned. They must not be ironed, but can be pressed readily with weights While the original Phofilm sunports slow combustion, Tensolite contracts so rapidly in the presence of flame that it actually runs away from the flame

THE average smoker lines has lungs with 8 quarts of tobacco tar in a period of ten years, according to the estimate of Dr. Angel H. Roffo, of Buenos Aires, Argentina.

SULFAMIC ACID

RECENT development of a practical process for commercial-scale manufacture of sulfamic acid (HSO,NH1) has stimulated a wide interest in this new industrial chemical. According to Industrial and Engineering Chemistry, a number of industrial uses based on the unique chemical and physical properties of the

With simple equipment amateurs can make sound-on-disk talkies

acid have already been developed. One such use is based on the rapid reaction of sulfamic acid with nitrites to yield nitrogen and sulfuric acid.

A novel industrial application of this reaction is its use for the necessary removal of excess nitrite following one of the steps in dve and lake color manufacture. Sulfamic acid is two to six times more effective than ures which is commonly used for such purposes. Higher concentrations of nitrite may be employed, and the excess nitrite removal in most cases may be shortened from a period of hours to a period of a few minutes Cleaner shades of color and greater un formity are thus made possible.

FLUORINE FILTERS OF BONE

N some sections of the country, mottled teeth have become a serious problem because of the fluorine in drinking water This cause of unsightly teeth, discovered only a few years ago, has set many research scientists working on ways to eliminate it Dr. H. V. Smith of the University of Arizona. College of Agriculture, reports some success in this direction

Dr Smith has invented a small filter cartridge, adaptable to drinking fountains. and made of bone Another type is larger and suitable for treating the water supply of schools or homes. An electric alarm is set off when the filter in the latter type has absorbed all the fluorine it can and hence needs replacement

The bone filter is made by treating animal bone with caustic soda, then washing it with water and finally neutralizing it with a dilute acid

ARC-WELDED STEEL RIVER TUNNEL

HICAGO'S new river tunnel, a double tube of steel, 200 feet long, 40 feet wide, and 23 feet high, which is to carry State Street subway cars under the Chicago River, is the most intricate job in Chicago's new subway system The giant tube will rest in a trench dredged to a 30-foot depth below the river bottom and will be sealed at both ends, towed 15 miles to its site and sunk by pouring concrete on its top

Different from ordinary procedure in tun nel work, (which involves boring beneath the river bottom), sinking the section as a unit minimizes the depth of earth covering over it-five feet as against 15 with conven tional practice. The shallower depth has the added advantage of providing a slighter grade in and out of the tube than would be the case otherwise

How Effective Is ALUMINUM FOIL INSULATION?

R ECENT investigation of heat transfer coefficients has shown that a single sheet of aluminum foil placed midway in a horizontal air space with the heat flowing downward is equivalent to approximately three inches of corkboard in insulating value. With three layers of foil in the same space, the heat transmission is reduced to almost half that obtained with one layer.

The investigation also showed that the eye, while a good judge of reflectivity, cannot evaluate aluminum as an insulator. Surface films formed by exposure to laboratory fumes and dust, salt spray, and by normal use as a house insulator are readily visible to the eye, but decrease the insulating value very little.

AMATEUR SOUND MOVIES

COUND equipment for amateur movie addicts, available for some years, has made use of the regular film sound track which, of course, necessitates the use of photo-electric cells and auxiliary equipment. Now, for the first time, amateur movies in the 8 and 16mm sizes may be made with dialogue, music, and sound effects-all reproduced as perfectly as sound on film but by the use of a phonograph disk in the Syncrosound System, a product of Presto Recording Corporation

The entire sound recording and reproducing equipment is contained in a single carrying case that weighs less than 50 pounds. It can readily be carried by one man The cost of the equipment is about 1/10th as much as the lowest priced sound on-film equipment. The cost of the sound recordings themselves averages about 20 cents a minute of running time, or one dol-lar for a five-minute reel. The synchronization is automatic, requiring no supervision or adjustment once the picture is started

The sound recording and reproducing system can be added to any standard make of silent 8 or 16mm camera and projector It consists of a portable sound recorder, an electric motor drive for the camera, and a small attachment for the projector. The latter units can be installed for a few dol lars and they can be quickly detached if desired to make silent films

SLOW FREE

FLECTRIC motors, coils, solenoids, mag nets, and relays often have overloads which are not necessarily harmful but which, nevertheless, blow the ordinary type

BIGGEST PACKAGE OF PHOTOGRAPHIC THRILLS

At This Special Bargain Price!

Reserve Your U. S. CAMERA ANNUAL NOW! THE BOOK EVERY CAMERA WORKER NEEDS ... MORE EXCITING AND HELPFUL THAN EVER.

To photographer, U. S. CAMERA ANNUAL:
the one "must" book of the year Both Full the
editor and Judges of the famous yearbook study
files no to twenty thousand of the year's best prints
made by American photographer—both ansietus
and professional, known and unknown From this
wounten of print, they select the cream of the
year's copy—which forms the main part of U. S.
Camera Annuals

Camere Annual
In former years, this collection of the best
work of American phenographer—reproduced by
work of American phenographer—reproduced
from hundreds of Book reviewers and strictle
in provided inspiration and guidance for thoupast schievements. Editor T J Meloney this year
has added many new features to increase its value
to smbrinous camera workers.

Finer Printing, Better Binding

First is an improvement in reproduction. Each photograph in the book is reproduced in letter press—the consistent and most testful press. Of the consistent and the standard press. Of the standard paper and 130-line heldlore, more detail, brilliance and tonal vanistions of the original salon prints are preserved then possible by my other printing method.

Second new feeture is an improved binding that makes U. S. Camera a more beautiful, lasting addition to your library than ever before—and at no change in price!

More Articles, More Inspiration

Third bug feature is its editorial content: this year it is more than a salon-in-book-form. It has more fine pictures than ever before, but in addition it has more articles and data than ever before! It is a book to read and study, as well as a book to look at

SUMMARY OF CONTENTS

Here is a partial list of features of U. S. Camera 1940:

Over 250 pages containing beautiful reproductions of the 300 greatest pictures of the year. Edward Steichen, sole judge, also contributes a stimulating commentary on Photography today.

Edward Weston's Guggenheum Portfouor a twenty-four page section entirely devoted to Bd-ward Weston's famous California photographs. Mr. Weston also writes a fascinating description of how this mountements were was often, the reasoning back of it, and the problems involved!

Hundred Year's of Photography by Elizabeth
McCantland: This wall-known writer on pho-

tographic subjects traces the contributions of this exciting art—not in terms of its early phases but its place in the contemporary American scene

Bigger Color Section Better than ever this year because of the improvement in color technique. Bigger, too: full page reproductions from fine process plates, of the work of America's leading color photographers

ing color pholographers

Greatly Enlarged Data Section Still more complete data on exactly how each picture was made,
with all equipment listed, and this year biograph
ical and personal data on the pholographer him
stil!

Special Features 1939's outstanding newspictures Groupings of unique texture photo graphs contrasts and humor shots breathtaking serial panoramas amazing at souther photographs documentary pictures potratis and pretorials, nudes and illustrations that excite, entertain and stimulates.

none that excite, entertain and rimulate!

Reserve your copy todey! Last year's edition was entrely sold in a few weeks So avoid disappointment by enterving your personal copy or the year—and for years to come (Remember, only one primiting, when that's 2004, on more will be available!) And despite all these Sold, on the sold of the sold of

SUBSCRIBE TO U. S. CAMERA MAGAZINE TO-DAY!

A SOLID YEAR OF PHOTOGRAPHIC INSPIRATION AND INSTRUCTION AT VERY LOW COST.

Would you like Ansel Adams to tell you how to photograph Architecture, illustrating his points with a series of magnificent prints of a California ranch-house?

Would you like to hear about Paul Strand's work and photographic philosophy from Elizabeth McCausland?

Would you like to see a collection of Toni Frissell's best work, and have Frank Crowninshield tell you how and why she does it?

Would you like to see the scores of prize-win ning pictures from the many thousands entered in the U S Camara Magazine Competition? Would you like to know how Barbara Morgan photographs the modern dance? How Elliot Elisofora does his documentary pictures?

Elisofon does his documentary pictures?

Would you like to see and hear how the famous
Art Center School of Los Angeles works?

Would you like to know more about the work of Lejaren, Hiller, Alfred Steiglitz, Martin Munkaesi, Valentino Serra, Biliot Porter, Margaret Bourke-White, and dozens of others?

Many Exciting Features

These are just a few of the features in coming issues of U S Camera Magazine—America's coalisest and most exciting photographs, publication As it enters its second year, now firmly stablished in the front rank, this ambinous magazine intends to make each issue bigger, more instructive and simulating that previous issues

Giving Readers What They Want

In the next six big issues of U S Camers you will see a more thrilling collection of analytical stricks, stimulating commentaries on spherical stricks, stimulating commentaries on spherical stricks, and the stricks of the stricks o

So make sure you won't must a single one of these next six issues of U. S. Camera. You can have each issue delivered to your home or studie flat and securely packaged, and you'll issue real money bender if you order your copies in combination with U. S. Camera Annual 1940. of fuse so that service is interrupted while new fuses are put in place A new fuse, recently developed by Littletius Incorporated, as of unique construction, designed particularly to prevent such interruptions it has a simple fuse link, a resistor element which provides the heat inertia, or time lag, and a spring

On severe overloads, the fuse link melts as a convential fuse would do, on prolonged but not severe overloads, the reasstor heats up and melts the fusible alloy. The spring serves not only to open the circuit completely after the fusible link has melted, but also takes up the expansion of that link due to repeated heating and cooling.

SHOULD EXPECTANT MOTHERS SMOKE?

SMOKING does not have any good effects on the mother during pregnancy flowever, chineal experience would indicate that a moderate use of tobacco is not harmful to the mother or to the baby. When a woman smokes excessively, it is usually suggested that she decrease her smoking during pregnancy and particularly during the nursing period.

Many physicians feel that the motione in tobacco may have a deleterious effect on the baby, but there is little scientific evidence to substantiate this view. Nicotine, however, does pass through into the mother milk, so that excessive smoking may result in toxic amounts of motione being absorbed by the child.—Journal of the American Medical Association.

ILLUMINATED TRAFFIC MARKER SET INTO HIGHWAY

OF the numerous attempts that have been made to provide safety markers for highways for right driving, one that seems to provide more positive Illumination than any other so far deressed is had defined by the source of Illumination of Ill

When Mr Greene first conceived this idea he consulted with a number of people regarding a transparent material which would stand traffic wear Some people told him the scheme was impractical, but he finally found that a transparent plastic would withstand not only the weight but also the surface wearing effect of passing cars and trucks. In accompanying illustrations we

Above: One unit of the illuminated traffic marker. Below A plastic test block set in a busy highway

show a sample unit of the illuminated guide ine and also a picture of a test block of a plastic material made by Monaanto Chriscal Company which was set in a busy street of Little Rock, Arkannas, for nine months. At the end of that time, during which an average of 9000 cars per day spased over it, the plastic substance showed no apparent deprecation of the surface and health was considered.

SCIENCE TO THE AID OF

N OT all inventions are made with a definite use in mind Only too often one may result from a great amount of research and then much more research is necessary to find what it is good for Polarioid, a material which polarizes light, falls in exactly that class. Originally, it was con-

sidered for an important use in the headlights of cars to which it has not as yet been adapted. It had, of course, a definite place from the beginning in scientific work, but practical everyday applications had to be found for it. Work to that end has found for it a place in many industries.

It may, therefore, not be so surprising to learn that this rapidly growing invention has been adapted for the beauty parlor Because of the ability of this material to dampen light reflections, as we have explained before in these columns, it has been found to be an excellent medium through which to view the skin and see those ble ishes which are partly or wholly invisible under ordinary light. Dr. Martin Grabau recently demonstrated in the salon Helena Rubenstein what is called the "Polaroid Dermascope," which employs this material. With it, it is claimed that an observer can examine layers of skin under the epidermis almost as though the outer skin surface were not there. Then by moving a control lever, he can throw the outer surface into even greater prominence than under ordinary light for the examination of surface blemishes. The assumption is that once the beauty specialist knows of the existence of hitherto unseen blemishes she can adapt her procedure accordingly!

PRESERVING PAPER

A NEW and improved method of protect ing documents, developed and patented by Dr Joseph Broadman, will strengthen paper by means of a protective coating which renders the sheet impermeable to air, moisture, and the like, so that it can be handled and preserved indefinitely. The coating does not increase reading difficulty.

In this process, a page of a newspaper, for example, has affact lo each face a thru sheet of transparent paper, preferably of that type known in the trade as "leastire". These sheets of light-permeable paper at alid on the newspaper with any autable adheave, preferably a paste of cold water and wheat flour. They are then allowed to dry at ordinary room temperature. The sheets of transparent paper increase the strength

"Polaroid Dermascope" and, top, skin under ordinary light (left) and polarised light

and tearing resistance of the newspaper, so that it can be handled without crumbling. But the transparent paper alone will not protect the page from the effects of air, moisture, and age, so the Broadman Process provides a coating on both faces and the edges of the transparent paper-covered sheet, thus, hermettelly scaling the printed or

thus hermetically sealing the printed or written matter against deterioration.

The protective coating is a composition

The protective coainig is a composition consisting of a mixture of 25 parts of Manila gum or Manila copal and 75 parts of child alcohol. East India or Pontianae gums may be substituted in the same proportion. The coating is applied by means of a rigid pad or spreading tool or perforated roller with a cloth covering, causing the formation of a light-permeable, smooth coating.

It has been estimated that about two or three seconds are required to add the "preserving" conting to a coated double page of standard newspaper size, at a cost of 12 cents per sheet. The entire process, including transparent paper and adhesive material, less than doubles the weight and thickness of the page of newspaper.—Shuley Frank

GROUP STUDY OF X RAYS

The Westinghouse multi-view stereorimens-onal X-ray potentizes to be viewed by groups of two to eight persons at a time Pol.t.red hight also is applied to X-ray work for the first time in X-ray history by the multi-view stereoscope. The old-fash-

Multi-view stereoscope, in which X rays appear in three dimensions

ioned interoption which used to adort
the parlor in the average American bone
composed in medican and increased average
accept work in medicine and industry. The
creation of a picture effect which shows
depth depends upon the presentation of two
images, taken from alightly different viewpoints. Each yee must inspect only that
image intended for it. This is usually accomplished by mease of micrors or prisms.
The polarized stereoscope employs two
images or transparencies made in the usual
manner. The method of illumination and
impection of the images, however, is new.

images or transparencies made in the usual manner. The method of illumination and inspection of the images, however, is new, arising from an interesting property of light. Two films are placed in illuminator boxes, see at zight angles to each other, and fitted with Polaroid screens. One illuminator has its acrees, arranged to produce vertical polarization; the other, horizontal polarization. A semi-transparent mirror is set on

From tough steerto TENDER STEAK

by Westinghouse

- When a friend unexpectedly happens to drop in for dinner, it no more than right that he take potluck for granted. But when we carefully plan a dinner, long in advance, most of us pretty much stick to the rule of serving the best food we can get.
- That rule was rudely broken last April, when one hundred and forty-six people sat down to dinner at a Cleveland hotel. It was a notable group—civic and industrial leaders, food experts, home economists, chefs, editors—people invited for one particular purpose, to taste a new kind of steak.
- They were not served choice beef; those steaks were not expensive. Average in quality, average in price, average in every respect—but one! This beef was treated by a new process, called Tenderay, which has the peculiar ability of making ordinary beef as tender and juicy in just three days as the expensive cuts the very finest hotel serve affect three or four or five weeks' aging.
- The guests were delighted. The steaks, they said, were excellent. But they were not half as pleased as Mrs. Cleveland housewife who learned that from that day on she could buy the same kind of beef at her own store. Heard that for the

- first time she could buy steak without guess and without gamble and know that it would be tender always.
- The Tenderay process depends on a lot of factors; humidity, temperature and what not. BUT—and here is where Westinghouse research plays such an important part—the process would be utterly impractical without the newly perfected *Sterilamp which kills bacteria with light and keeps the meat fresh and sweet.
- · He would be a rash prophet who'd care to predict the uses commerce and industry and medicine will find for the Sterilamp. In Suffern, N. Y., a bank installed it over the teller's windows to keep germs from passing with the money. A poultry man says it solves his turkey raising problems. Restaurants, hotels, bars and soda-fountains-in ever increasing numbers-depend on Sterilamps to keep glasses sterile; meat markets and groceries to keep food fresh, to reduce spoilage and refrigeration costs. One of the country's largest hospitals has installed Sterilamps to sterilize the air in the operating rooms. Another in the nursery to protect babies in their
- Certainly Westinghouse, when this development surted, did not know its ultimate scope. And that, after all, is the way of research and its great justification. It is an exploration into the unknown, it follows new paths and uncharted byways—not with the assurance of success; merely with courage and experience and knowledge, and sound common sense as a guide.

a diagonal midway between the illuminator boxes. Each observer looks through a pair of polarizing spectacles. Looking into the semi-transparent mirror, the persons at the left see one image reflected in the mirror, the other transmitted through it. Each eye sees only the image intended for it and each with the same brilliance. The new apparatus permits a group to discuss the same image, at the same time that they are viewing it

ELECTROPLATING PLASTICS

E LECTRO-DEPOSITION of various types of synthetic resinous materials on metals by a new process was described in a recent issue of Industrial and Engineering Chemistry. The process involves the solution of the resin in an organic solvent and the subsequent formation of a suspension in mineral oil

The work to be plated, which may be copper, tin, or brass, 1s placed in the suspension and direct current applied. Satisfactory results were obtained, using 300 volts for five minutes. After the plating has been applied, the plastic is cured or not, depending on the type. Tests showed that the deposits are satisfactory from the stand point of electrical insulation. The process has been used experimentally for coating small trimmer condenser plates.

BUNA

GERMANY is equipped to manu-facture about 25,000 tons of ar-tificial rubber yearly, as compared with a peace-time need of 100,000 tons of rubber per year.

REFRICERATION

AFFECTS FLAVOR

REFRIGERATION of many fruits and vegetables, as housewives have often complained, destroys the rich, delicate flavor for which those products may be noted. This is particularly true of tropical fruits such as bananas, pineapples, mangoes, and avocados. It is also true to some extent for fruits grown in the temperate zones. Some varieties of pears, if held too long at 32 degrees, lose their ability to ripen and 'go dead."

To prevent loss of flavor and texture, tropical fruits and pears should not be chilled until immediately before serving.

CIRCULAR SEAM WELDING

AN engineering advance has recently been made by the Chicago Metal Hose Corporation in the attachment of metal endfittings and end-seals to metallic tubing by means of electric resistance welding. development, designed principally for use with stainless steel tubing and stainless with stainless steel tubing and stainless steel bellows, permits the fabrication of completely sealed vacuum-tight units free from soldered, brazed, or torch welded joints of any kind.

End fittings made from stainless steel have been customarily silver soldered to stainless bellows and tubing where corresive media or high temperature were to be encountered. However, to meet conditions

where exceptionally high temperatures and actively corrosive elements preclude even the use of silver solder, electric resistance welding has unique application.

Circumference seam welding, made possible through the development of specialized oquipment, operates automatically and eliminates entirely the human element present in other welding or soldering procedures. Extremely, this gases of metal can be

Extremely thin gages of metal can be handled with case, and metals of unlike thicknesses or unlike analyses can readily be joined.

TRANSPARENT PLASTIC HEEL

A NEW plastic heel is now available in sides its transparency, it has the novel feature of a removable lift. As the lift wears down, it may be taken off and a new one snapped into place. The heel is a product of the General Electric Company's plastics division.

The accompanying picture is of a transparent model showing the construction. A

plastic of the polyvinyl methacrylate type is used for the heels. They are waterproof, noninflammable, and give a touch of sparkle to almost any costume.

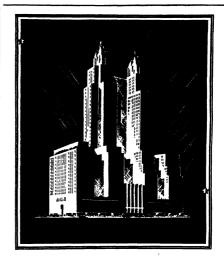

Some of the heels were "neonized" recently for stage use by the St Louis Muniipal Opera. They produced a striking effect on a darkened stage.

ACID HEALS PLANT WOUNDS

WOUNDS in plants are caused to heal by an acid which has been isolated in crystilline form by research workers of the California Institute of Technology. The name "traumatic acid" was proposed for the substance which is identical with the organic acid. I-decemen-11/dicamboxyline of a more detailed statement to be published later, induced rapid formation of bealing tissue on the cut surfaces of potato tubers by using a solution of the synthetically prepared acid.

FROZEN SERUM

ables biologicals to retain their potency long after the time which, until now, had been thought to be their expiration date

The Lyophile process, as it is called, was developed at Mulford Biological Laboratories and is essentially one of rapid freezing at a temperature far below the freezing point, together with rapid dehydration under high vacuum without melting or fusing the original frozen substance.

The containers are specially designed to maintain the desired vacuum and are so constructed that into the neck of each there may be inserted a tightly fitting rubber stopper. This is done after dehydration is completed and without breaking the vacuum When the stoppers are in place, the containers are flame sealed, labelled, and are ready for shipment,

The physician who uses the serum finds it a simple matter to restore it to liquid form. After filing and breaking off the neck of the container, a sterile syringe filled with distilled water is inserted through the rubber stopper. The vacuum draws in the water and the material readily dissolves, taking on the original properties which it possessed as a freshly made serum in the houid state.

The new process brings to the physician, and ultimately to the patient, the original curative value possessed by a freshly pre-pared substance at the time of its highest potency.

AIR CONDITIONING

N 1933, there were only about 40 air-conditioned passenger cars on the American railroads, and most of them were diners. Today, the railroads and the Pullman Company operate 11,351 air-conditioned passenger cars.

BIG OIL MOLECULES

FROM SMALL

SQUADRONS of German fighting and bombing planes now flying in Europe's skies are being lubricated by oils made by treating mineral, vegetable, and animal oils with an electrical discharge process which increases their viscosity. The "voltolized" oils, as they are known, are then blended with ordinary mineral oils to pro-duce what is said to be a superior airplane lubricant which has many of the valuable properties of castor oil.

The action of the electrical discharge appears to produce polymerization of the molecules of the oil (make large molecules out of small ones) and does it without changing the essential properties which make for good lubrication.—Science Service.

NEW TYPE BIG TREE

MOVER

BIG tree moving is now an established practice in landscaping properties and it is only natural that labor-saving equipment has been devised to keep costs lowered and generally to increase the speed and efficiency with which large specimen trees may be moved and transplanted. Over a period of the last 10 years, an

efficient type of tree-moring orquipment known as the Butts Tree Mover has been developed under extensive field tests. It is compact, requires less hand labor, is readily mobile, and handles trees with speed and safety. Constructed of electrically welded steel and with all fast-moving parts equipped with ball or roller bearings, it should give years of dependable, troublefree servee.

The equipment consists of a complete unit which can be installed on any truck having a minimum of nine inches from rear spring shackles to back of cab. It is so designed that the cradle, in which rests the trunk of the tree to be moved, pivots in two directions, this factor, together with

Cradle end of the unit employed for transporting large live trees

chain suspension, insures proper support for any size or shape of tree. A sec cradle, adjustable both in size and in its relation to the trunk cradle, is attached to the rear of the boom, supporting and pro-tecting the ball of earth which may be up to 10 feet in diameter. The boom rolls on its hinges and is lowered to ground for loading. When transporting the tree, the boom is carried up and forward by a power winch driven by a 15,000-pound worm drive. An eyebolt, attached through an adjusting winch to top of boom by cables which pass on each side of the tree, is placed through the ball of earth and affixed to a horizontal plank underneath. cables in turn are connected to a heavyduty canvas belt behind the tree trunk to simplify tipping and guiding of the tree.

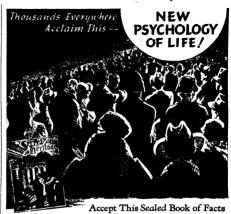

Carried in a horizontal position with the top forward, the tree rests on saddles at each end of the boom. This latter is opersted by roller chain and worm driven sprockets, which control tipping of the boom downward and a leverage, powered by the same roller chains, controls upward tipping of the boom.

The Butts Tree Mover is also used in

The Butts Tree Mover is also used in pulling and loading stumps and is well adapted for use on many kinds of construction jobs.—C. F. Greeves-Carpenter.

New Synthetic Solid Produces Unusual Tracing Paper

AN entirely new type of tracing paper A combining the transparency of oil treated shoes with the permanence of natural 100-percent rag papers is a recent development of the Kenfeld & Keer Company. The new paper is named Albanence it is made of long-fiber, clean, white rags, and is treated with a new crystal-clear synthesic solid called Albanite, developed in the company's laboratories. Because this way transparenting agent is free from oil

HAVE YOU unrealized hopes? Are the better things of life always just beyond your reach?

Times have changed—but have you? Do you still believe that some were born to have eventful lives—to have fame, fortune, and power, and still others destined to be mere plodders? Are you able to demonstrate a change in your affairs, to put your circumstances in order, and move forward to a better station in life? If not, it is time that you adopt a new psychology of life and learn to MASTER YOUR PROBLEMS.

It takes no greater mental effort to achieve results—when you know how. Successful living is the oldest art in the world. It consists of developing initiative, foresight, and the ability to combine experiences into new and workable ideas. The knowledge of this art was acquired in centuries past through the personal sacrifices of the ancient sages, who dand it investitated life's mys-

teries. Their discoveries of the secret functionings of man's mind have been preserved by the Rosicrucians, an age-old, world-wide fraternity (not a religious organization).

The Rosicrucians Offer To You

—if you have the courage to break away from limited forms of thinking, these same simply expressed truths of life, which have led thousands to a joyous method of better living. If you are sincere—use the coupon below and secure the fascinating /ree book, "The Secret Heritage," which tells how you may receive this knowledge.

and wax and is chemically and physically inert, it is claimed that Albanene will not oxidize, turn vellow, become brittle, or lose transparency with age.

It is claimed that the use of this new type transparentizing agent permits a fine toothed, smooth drawing surface that takes strong pencil lines with a minimum wear on the point.

RAILS

BY using a welding process for building up the worn ends of steel rails, the life of these rails is prolonged fully one third.

PROTECTING COPPER SURFACES

THE New York World's Fair, besides THE New York World's Fair, besides being an extraordinary speciacle, proved to be a testing ground to show the lasting qualities of paints, colors, and pro-tecting coatings. Of particular interest is the use of Glyptal, an alkyd resin, which has proved its ability to maintain the luster and characteristic color of copper sheets which it protects. On the exterior of the General Electric Building are thousands of square feet of thin copper sheets, protected with a coating of this material, which have retained their pristine appearance during many months of exposure This first actual long-term test of Glyptal under such conditions indicates many other possibilities for its use in many industries.

ELECTRIC FURNACE USES BLANKET OF GAS

R ESEARCH metallurgists have intro-duced a new steel-hardening furnace that uses a "blanket" of gas to prevent "singeing" the metal while it is toughened at temperatures as high as 2000 degrees, Fahrenheit.

By means of a delicately balanced atmosphere of pure hydrogen and nitrogen, this automatic electric furnace is able to harden many steels gently without quenching them in oil or water, thus climinating distortion and formation of scale.

The furnace is approximately seven feet

ARISTO IMPORT CO., INC.

Air-hardened steel scratches glass, approaches the hardness of diamond

long and so designed that a piece of steel passes through it at varying stages of heat, ranging from approximately 1300 degrees to 1750 degrees. Pathernebit, before it cools in an air-coded tunnel. Maintenance of an anatrosphere of oxygen-free gases inside the furnace prevents any reaction in the steel which would dutor tor mar the metal. The steel shows no outward evidence of having passed through the fiery order.

Precess of ordinary steel, polished to a mirror finish, retain their finish after a fourhour hardening treatment in the new apparatus, report Westinghouse engineers. The same steel would burn up if it were subjected to such high temperatures in an ordinary furnace, because of the oxygen in the atmosphere.

The combination of controlled atmosphere and temperature now enables the metallurgist to harden steel pieces in their finished form with a resultant bright finish and without the expense and delay of additional machining.

INCREASING THE BEARING CAPACITY OF PILES

RECENT investigations for the purpose of economyring pile foundations have developed an interesting method for increasing the bearing capacity of piles by covering them with a thin sheet of aluminum metal and sending an electric current through the soil. Preliminary small-scale tests performed revealed the formation of an entirely new and hardened soil structure in the vicenty of the electrode. Tests also revealed that the hardening is not simply drying of soil, but it irreversable on the soil by the electrical process, cementing the migral particles of the soil.

With small-scale tests, the bearing capacity after treatment increased up to between 10 and 30 times the original. By pulling the piles, the hardend section around the electrodes can easily be seen. Large-scale tests bridge foundation. A few timber piles about 60 feet long were covered, up to about 25 feet with thin aluminum are about 25 feet with thin aluminum after withinty of the common piles without aluminum. The distance apart of the aluminum piles was between six and seven feet, and electric current was sent through at between 90 and 220 wolls. Though the subboul conditions

AFRIAL MAPPING FOR HIGHWAYS

THE fastest and cheapest way to secure an inventory of any area is to have it photographed from the air. With highway planning now covering whole states and requiring more and more inventory data, modern methods of mapping based on aerial photography have recently been developed to permit economic methods through the use of simple instruments and devices

In making topographic maps by stereoscopic methods, the camera used for aerial photographs is of the precision type. Flying is done systematically so that the required overlays, both in the direction of flight and sideways, will be consistent. An aerial photograph does not show any depth, but with two photos partly overlapping and taken from different positions, it is possible to adjust them on the table at a certain distance from the eyes so that there are two images which merge into one having depth in addition to previous characteristics. To aid in viewing, a stereoscope is used.

Where the nature of a contemplated project involves the purchase of land, it is safe to say that the mapping of property by this method on a scale of 1:12,000 is just as accurate as if the surveys were made by transit and tape plotted to this scale.-Eric Haquinius, in the Texas Engineer.

TRICHINAE IN AMERICAN SWINE

TRICHINAE, the muscle-boring paraally fatal illness in eaters of inadequately cooked pork, are widely distributed in the United States, reports Dr. Benjamin Schwartz of the U. S. Department of Agriculture. In grain-fed swine, however, they are not nearly as abundant as in those fed on garbage. On the basis of thousands of examinations of slaughtered animals, Dr. Schwartz gave the percentage of trichinaecontaining carcasses as less than 1 for grainfed hogs, whereas it was 5.7 percent in garbage-fed hogs. The greatest bulk of hogs slaughtered in the United States, Dr. Schwartz added, are grain-fed.—Science Service.

SOLUTION TO THE PROBLEM OF THE WEIGHTS

AST month the problem offered was one concerning a set of eight weights for to be capable of weighing to the nearest ounce any object up to, and including, 205 nounds. Each could be used on the left scale pan, on the right, or not at all. It was required to find the magnitude of each weight, prove that eight is the least number, and that the eight weights have the least total weight of any set which will fulfill the conditions of the problem.

Solving for the first part we reason that, to weigh one ounce, it is necessary to have a l oz. weight In order to weigh two ounces we may select an additional 1 oz weight, a 2 oz. weight, or a 3 oz weight. We choose the 3 oz., because together with the 1 oz. weight it will enable us to weigh not only 2 oz. but 3 oz. and 4 oz as well. Similarly. in order to weigh 5 ounces, we select a weight equal to two times the sum of the weights already chosen, plus one For example (2) (4) $\pm 1 = 9 \text{ oz Reasoning thus.}$ it follows that the eight weights are 1, 3, 9, 27, 81, 243, 729, and 2187 ounces; a total of 3280 ounces, or 205 pounds

Solving for the second part, we see that since there are three places where the weights may be placed, there will be 3° different distributions of them From this number we subtract one to account for the case where all weights are on the shelf. The remainder is divided by two because for each "out of balance" on the left side there is one on the right. This evaluates to

$$\frac{3^{4}-1}{2} = \frac{6561-1}{2} = 3280$$

It is apparent from the nature of the formula that a number smaller than eight for the exponent of three will give fewer than 3280 weighing combinations, which was a con-dition of the problem Eight is therefore the least number of weights.

For the third part of the problem, obviously it requires a minimum of 205 pounds to weigh that much on a beam balance. Since the eight weights add up to only that amount, it follows that they have the least total weight of any set which will meet the conditions of the problem.

esented before a meeting of the American Chemical Society. Dr. Cadwell is director of tire development at the Detroit plant of United States Rubber Company

This somewhat astonishing conclusion is the result of a series of scientific tests and a research over the past three years in the company's laboratories, Dr. Cadwell re-The scientist was reserved in his report and comment, but other researchers pointed out that the discovery new positives of great importance to industry and

Dr. Cadwell told the Society his conclusion rested on the remarkable fact that rubber differs from most, if not all, other natural materials in that the "harder rubber is worked the greater its mechanical fatigue life."

"Indeed," he reported, "if rubber is used properly as a spring it can be made even to outlast a steel spring. If metals are to be worked in vibration, all engineers know that the longest life can be expected for a unit in which the metal is under minimum stress or load. For rubber, the opposite is true: the shortest life occurs when the rubber is worked under low loading or low etress conditions

LOW-TEMPERATURE FIRING FOR NEW

CERAMIC MATERIAL

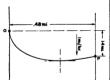

THE high cost and hazard of kiln firing, which often discourage ceramic and pottery work as a hobby, school craft, or small commercial venture, have been banished by the development of a new clay by Ettl Studios, Inc Ceramite, as this clay is called, requires no treatment other than baking in a kitchen oven for 20 minutes at 250 degrees, Fahrenheit, to produce a product having greater durability than ordinary clay fired at 1800 degre-

Also available is a full line of color glazes which can be applied with a brush or spray, blended or applied over each other, and rendered permanent by oven baking for 45 minutes at 250 degrees, Fahrenheit.

PROBLEM: THE SWIMMING DOG

FOR the past few months we have been P offering our readers a variety of mathe matical problems. Judging from the letters received, many people have really enjoyed wrestling with them There seems to be a sort of esoteric satisfaction in arriving at a solution after an hour or so of brain work Can you solve this one?

A man is standing on a river bank, on the opposite bank is his dog. The man whistles and the dog, being well trained and very obedient, jumps into the river and starts swimming, always headed towards his master. The man is represented by "O" in our diagram, and the dog's starting point by

"P." The river is 0.48 miles wide and the dog started from a place 0.14 miles below a point directly opposite the man. (In other words, the man and his dog were a half mile apart.) Now, if the river flows at a rate of one mile per hour and the dog swims at the rate of two miles per hour, how long will it take him to swim the river? Remember that at all times he is swimming towards point "O". The answer is 22.8 minutes and we will publish our solution next month.

As usual, any correspondence relative to this or any of our previous problems should be addressed to Lieutenant-Commander Leonard Kaplan, in care of Scientific American, 24 West 40 St., New York, N. Y., and it will be forwarded unopened.

YOUR FIREARMS

Conducted by A. D. RATHBONE, IV

INTEREST IN FIREARMS is traditional with American men; science has so developed them that millions yearly find sport and recreation in their use. Hence this monthly department presenting a whee variety of discussion regarding frearms, their handling, and their accessories. Suggestions from readers will be heartily welcomed.—The Editor.

TENITE STOCKS

HETHER or not we've all been aware of it, this stuff called Tenite has been with us in many ways for some time. Both hands have clasped it as we've gripped the steering wheel of the car; we've pounded it in typewriter keys, admired it in radio grille-work and twirled in Europe with Tenite dial knobs. We have yanked it in handle form when we robbed the refrigerator, stirred cocktails with it and even mixed ingredients of said cocktails with a Tenite jigger But it remained for J. Stevens Arms Company, Division of Savage Arms Corporation, to go almost lock, stock, and barrel in the use of Tenite. Equipped with foreend, stock, and sight-piece of this plastic, the new Stevens No. 530 M double-barrel shotgun in 12, 16 and 20 gage has caused something of a stir in firearms circles.

Product of Tennessee Eastman Corporation, Tente is made from Eastman cellulose acetate, as thermoplastic and adaptable to both compression and injection modding, its attributes for gun stocks are low thermal conductivity, low water absorption, and conductivity, low water absorption, tensile strength of about 4000 pounds per square inch. In conducting fing tests, a Tente stocked abotgon was clamped in a shooting jack, shoulder poece resting against a solid block so that the stock reveved the full gun recoil. After repeated firing, the hard rubber butt-plate cumulied stock showed no fracture or distortion.

Shortly after the Stevens announcement, criticism was leveled at the alleged shrinking tendency of Tenite when exposed to a maintained temperature of 140 degrees, Fahrenheit. It was likewise charged that Tenite would soften and possibly warp in a continuous heat of 160 degrees, Fahrenheit, that acid or alcohol might blemish or soften the smooth, walnut burl-like finish. Although disapprobation was also expressed concerning stock measurements, we're momentarily more interested in the ability of Tenite to "take it" than in gun specifications. However, here's how Stevens lists them: gun 14 available in 12, 16 and 20 gage with blue forged steel barrels, matted rib, fitted with two white bead Colasta sights, in 28 and 30 inches for 12 gage, 28 inches in 16 and 20 gage. Right barrel is modified and left is full choke, chambered for 2%-inch shells. It is hammerless; has checkered, full-pistol grip, capped; fluted comb; paneled sides; 14 inch stock; drop at heel of 2%, at comb 15% inches; positive extraction; and weighs from 6½ pounds in 20 gage to 7½ pounds in 12 gage.

To determine effects of chemicals and reagents on Tenite, Tennessee Eastman Corporation conducted a series of tests in which dried, weighed, and measured samples of the plastic were immersed for 84 hours in 85 different acids, allalies, asits, alcohols, organic esters, solvents, essential solution, organic esters, solvents, essential solution strengths. From this list we endeavored to select those regents to which a gun stock might normally be expected to be exposed in the gamet of carries human other chemicals of the solution hydroxide, and other chemicals not customarily found on the sportsman's person or in his kit. This left us with alcohol (ethanol), gasoline, benzene, turpentine, nodine, mercurochrome, curre acid, and oils cittrorella, ecuslyptus,

Stock, fore-end, and sight piece of a new shotgun are of Tenite

lemon, pennyroyal, and wintergreen, concerning which Eastman tests showed that henzene produces a "slightly blustering," oil of wintergreen a "slightly rough surface," sodine a "brown timi," mercurochrome a "pink timi." Otherwise, "no change" was reported in the surface of Tenite after exposure to these reagents which we selected from the entire 95.

Not doubting the Eastman laboratories, but solely in an effort to test Tenite with both reagents and vicissitudes to which an extremely careless gunner might uninter tionally expose his gunstock, we conducted a few "home-made" experiments. We pr cured samples of the plastic and smacked one piece with a hammer to simulate a hard fall or a blow of the stock against trees and rocks. The result was a much smaller dent than the same force would have made in a piece of walnut. We sacrificed a bit of 90-proof whisky in a 24-hour immersion test without effecting the slightest blemish. Lemon juice, gasoline, iodine, mercuro-chrome were all negative, save for the expected stains from the latter two reagents. We laid a lighted cigarette on a slab of Tenite and allowed it to burn to the end-The result was exactly what we've been chastised for in the instances of the piano and the drop-leaf table.

As to the danger of a maintained temporature of 160 degrees, Fahrenheit, Frank T Green, Assistant Superintendent of the Stevens Company says, "... among our laboratory tests, we subjected a stock molded from this material (Tentice), to a test in a closed electrical over where temperatures could be maintained constant for a long period of time, and we were able to subject these stocks to a temperature of from 100 to 200 degrees, Pakenchici, without any apparent distortion." We shudder to thank that any person could conceivably do to his gunsteck all that was done to Tente and we rather thank that, mosfar as its durable qualities are concerned, the results speak for themselves.

FOR GUN COLLECTORS

T'S a far cry, indeed, from a Tenitestocked shotgun of the 20th Century to the Austrian made specimen of wheel-lock "sporting rifle" of 1665 which we recently inspected at the exhibit of the International Studio Art Corporation, formerly a part of the William Randolph Hearst collection, and now being disposed of Specifications of this rifle, expressed in the modern man ner, are: blued, octagonal barrel: fixed leaf rear sight for point blank shooting with adjustable folding leaf for elevation (fancy that---"elevation" in 1665†); rifled with eight, deep, narrow grooves; length, 44 inches, weight, 8 pounds, 541 ounces, caliber, .63

Not to know where or when one mast stumble across a really fine specimen of the early gunsmith's art, but to be able to evaluate such a find, and to couple with it all an active imagination, probably constitute the primary component parts of the fascinating hobby of amateur antique gun occletting. Our own imagination certainty needed no urging when, in runningging through tile laternational Studio's exhibit, we found the pair of dueling pistols which spat lead at each other on Saturday morning, April 28, 1826 For on that date, with those arm, at a secluded upon above Little those arm, at a secluded upon above Little

Dueling pistols that were used on the field of honor 113 years ago

Falls Bridge, Virginia, John Randolph and Henry Clay respectively sought and defended honor. No one was hurt, honor was vindicated, dueling went the way of the muzzle loader, and now, 113 years later, this fine pair of pistols is looking for a new owner. Meanwhile, our imagnation rambles on in the realm of ancient firearms and those who used them.

We've considerable interesting information on tap concerning the inauguration of amateur collections of old firearms and if you're interested in learning how to begin, where and what to look for, we'll be only too glad to pass it on.

EUROPEAN GUNS

AVAILABLE

NO one can prophesy what new twists the Egropean war will have taken by the time this appears in print, but we

have recently been informed by Abectromble & Pitch, Prancis Bannerma & Sons, and Stoeger Arms Corporation, three of our largest importers of foreign made sportsmen's arms, that the importation of those very excellent Belgaan and English shotguns and riles has not thus far been serously affected. Save for the German makes, where the situation is, rather naturally, somewhat different, imports are expected to continuous in sufficient quantity to manmin the properties of these firesame in the state of t

Although all British gun manufacturers are reported to be busily engaged in wartime operations, and although their pers nel has been affected by calls to the colors, Messrs James Purdy & Sons, Boss & Company, E J Churchill, Ltd., W. W Greener, James Woodward & Sons, and others are continuing to make the fine quality guns for which they have so long been famous, There has been no perceptible break in the import of Belgian firearms and save for a momentary lull at the outbreak of the war. British imports have to date proceeded normally. Despite the discuption of German shipping, Abererombie & Fitch have just Norway, of Greefelt triple barrel shotguns.

Pot-Shots

THOSE VACATION

PICTURES

THE vacation months are gone but the negatives remain, and with them your responsibility for carefully evaluating the merits of each and discarding those which, from every viewpoint, are of no worth. Among the discards will undoubtedly be sunrises and sunsets, mountain scenes with bald skies, certain landscapes, and so on-Even the best of us, carried away by a peculiar lighting or misled by a touch of color which might have been effective in color but not in black and white, take a number of shots during our vacations and at other times which bring disappointing results when fished out of the developer tank. Such incidents are nuggets of experience which are to be valued rather than deplored. The next time you will be more careful and hold your fire, or try some other angle.

Among your most interesting negatives will be those of people, particularly children. Some of them, because you may be possibly have had to work that and get your subject on the fly or were handicapped in some other way, may not be everything that might be desired as to composition. However, do not give up on this account; there ever, do not give up on this account; there is always the opportunity of taking a piece out of the negative and projecting it at a suitable angle. The "Rural Potratan" illustration did not present any great difficulty with this group of eight children of various ages. The stoop was conveniently handy;

the lighting would have been better if the faces were more in the shade, but the squinta here and there lend an atmosphere of humor to the picture.

Valued above others will probably be those puttures which illustrate your vacation experiences. An entire series or group of prunts may be assembled to illustrate the experiences of living at a farmbouse in the country. One such pieture is that of "Sunrise" taken at 6:30 o'clock on a September morning. In composing this pieture in the camera, it was thought best to concentrate on the outdoor scene and include only sug-

"Rural Portrait"

gestions of the oot on the left and the wooden bench on the right.

Inevitably, there will be sunset pictures Two examples that appear to have "come out" with fair success are "Sunset" and "Place's Pond." The former was shot on the way home from a short excursion. It seemed to deserve photographic attention because of the arrangement and shapes of the clouds and the interesting foreground which, of course, had to be shaded somewhat in printing to allow the greater print-"Place's Pond" was one of a series of shots during a sunset. The quality of the water and the delicacy of the sky made a shot

imperative.
"Barn Texture" is an example of the type

of shot that may interest both the pictorialist and the antiquarian. This also might be part of a series showing different parts of the barn, exterior as well, possibly, as the interior. The lighting has to be watched carefully, of course, in order that texture may be revealed in the most eloquent way.

In printing your vacation pictures, make a special effort to concentrate on a few negatives each session rather than attempt to work through the night and try, willynilly, to finish up the whole batch all at

"Place's Pond"

once. If you print only a few, you will know that your best work went into them because you will not be tired; if you print many, those towards the end of a weary evening are bound to suffer in quality.

When you are through with the negatives, return them immediately to their enclosures which should, of course, be pro vided when the negative strips are removed from the drying clips and cut up for filing It is so easy, when many negatives are being printed, to let them lie around after an evening's work, to gather dust and possibly suffer accidental nicks and scratches

Study your vacation negatives and see where this or that one may have been improved or why this one failed and that one is absolutely hopeless. You will learn much from such careful study that will help you not only during vacation next time but all through the other seasons of the year.

CLEANING LENSES

A PERIODIC cleaning of the camera lens should be one of your regular hobby duties. Carefully remove the lens from the camera and brush all surfaces with a camel's hair brush to remove grit and dirt. Wipe the glass with a sponge moistened in spirit. Make sure the sponge is absolutely clean and free of dirt. Finally, polish the surfaces with chamois. Or breathe on the surface of the glass and polish gently with an old, soft, and well-washed cambric or linen handkerchief.

LIGHTNING SPECIALIST

A FOUR-FOOT lighting rod erected on the tower of New York's Empire State building provides Bill Eason, General Electric engineer, with unusual picture material of scientific value, according to a story in The New Yorker. Mr. Eason's exclusive job during the thunder-shower season, May 15 to October 1, is to come down to New York, watch for lightning and take pictures of the bolts as they strike the Empire State. The dictures plus the data are relayed to the home office.

The equipment includes three high-speed cameras in a room on the 39th floor of the bailding at 500 Fifth Avenue, at Forty-

VOIGTLANDER BRILLIANT

Unique Mirror Camera with F4.5 lens in Prontor Shutter

The Brilliant V6 is unique because no other camera has such a large bright and clear view in the finder. A glimpse at the finder and you know whether your subject yields the desired picture effect.

Sport scenes requiring especially fast "follow up" with the camera are greatly facilitated by the frame sport finder in hood.

The Brilliant takes 12 pictures 21/4 x 21/4 on standard 120 film, has an automatic stop to prevent over-winding and a built-in "hold-all" compartment to carry filters, etc.

110 WEST 28HO ST N.Y

second Street; two oscillographs for recording the duration and intensity of lightning strokes, in the Empre State tower; and a fourth camera on the roof of a building at Eighth Avenue and Thirty-fourth Street, which gets the lightning "in profile." The latter camera is operated by remote control from the Fifth Avenue office.

When one of his storm tipaters rings Mr. Eason to taxi from their apartment at 10 Park Avenue to taxi from their apartment at 10 SO Fifth Avenue, while Mr. Eason hurries to the Empire Tower to start the oscillographs, after which he taxis to the Fifth Avenue office ready for action. Work is in the ready for action, and we have the start of the ready for action. As the works, Mr. Eason talks into a As he works, Mr. Eason talks into a

As he works, Mr. Esson talks into a microphone attached to his lapel, a record of his comments being engraved in wax, which Mrs. Esson transcribes the next day for the home office.

The Empire State has been struck by lightning 92 times in the last four years, but no one is ever hurt. Some of the strokes have exceeded 22,000 amperes and have lasted more than a second. It takes about sax-tenths of an ampere to light an ordinary 60-watt electro-light bulb

GLASS PICTURES WITHOUT NEGATIVES

IN a recent letter, E. L. Hettinger, of Reading, Pennsylvania, writes us about his experiences in the making of prints by enlargement in his special field of technical glass studies, and sends us a beautiful

Without a negative

example of one of the prints he has made.
"The matter of making inlargements without negatives," Mr. Hettinger writes, "has
been an old stunt employed many times in
my forty-five years" of experience. There
were times when we would take a piece of
lace, or a piece of geometric chipped glass,
and place it in the enlarger was no make a
border for some of our negatives. Naturally,
this all occurred in the old days when
things had to be fancy so as to be attractive. Later on, this experience helped me
in my work on heal-treated glass. The man
problem was to try to get some dota about

the harmonic vibration point of glass.
"To break thousands of pieces of glass and make negatives, and then enlarge them was far from satisfactory. Under these criminationes, I tried the old stunt of using the glass in the enlarger without making a negative. I found that little if anything

was lost in the print. In the illustration (reproduced here), a steel pollet hit the center of a prece of glass as shown by the inner circle. There was a vibratory motion, and then the energy dissipated from these concentric rings, and showed a fracture which again reverted back to the ring vibrations.

"Without trying this experiment, you would hardly know how much was lost in making a negative and then enlarging it. For this reason, I have adopted this method of making enlargements without making negatives, because it saves a lot of time, and one does not lose any of the minute details that are required for studying the subject."

JUST A DETAIL

THERE is a story going the rounds con-cerning the folly of being didactic among one's peers. It seems that a member of a camera club requested a fellow men to develop a dozen negatives for him. Presumably wishing to make sure that no mis take would be made in the processing, he gave complete instructions including the wholly unnecessary one of closing the darkroom door before beginning operations. All these instructions, to the very letter, were set down in writing, and were followed without change. However, one very important step was omitted there was nothing to the effect that the white darkroom light should be turned off before operations were begun. The darkroom worker mischievously went right ahead with all the other instructions, including the removal of the film from its covering in the ruinous light. Of course, the films were hopeless from the start, but he

developed, fixed and dried them, carefully wrapped them in with interleaving between the regatives and handed the finished work, very solemnly and innocently, to the owner. The latter stood aghast at the 12 black negatives but took the incident in good grace when his written instructions, with the fatal omission, was aboven to him. Lucklip, the pictures could be taken over again without truble, and were. The next day the didactic member again asked the same favor, but this time the amoby and: "Will you nlesses

develop these for me?"

A SPECIAL effect, full of warmth and glow, is obtained in portrait lighting by having the subject partly illumnated from below, as in the illustration, "Mary Ellen." This type of lighting is usually called "dramatic" but when so employed it

"Mary Ellen"

ordinarily constitutes the main and only light used. However, a softer effect is obtained by having the light come from above, back of the subject and reflected from below by a reflecting screen so placed as to give the effect sought. This was the procedure in the present instance.

AWARD FOR

CAMERA HEADLINER

FOR the best foreign newareal of the year, A. T. Hull, Ir., of Pathe, says an announcement from the makens of the Licia, was awared the plaque of the National Headliners Club at a dinner held creently in Atlantic City. The film for which he was given the award showed the triple holoscape of the bombling of Canton. Like many of the cameramen covering the hostilides in China mitimally used it for making stills, many of which have appeared in Life and other national publications.

SPOTTING KINKS

DLACK lines and black spots on prints, caused by transparent lines and holes in the negative, are usually more difficult to remove than spotting out light defects. One effective way to remove both lines and spots

PRIZES

EVERYONE who owns a camera
has a chance of winning a valuable prize Plan now to enter your
prints in this contest You may enter
any or all of the three divisions, but not more than two prints may be en tered by one contestant in any one of

Specific rules for this contest are pubished below. Be sure to read them

RULES of the Contest

- The groups will be judged independently on the basis of pictorial appeal and technical excellence. The decision of the judges will be final. In case of a tie for any prize, duplicate prizes will be. rded to the tring conte
- 2. Prints must not be smaller than 5 by 7 or larger than 11 by 14 Prints need not be mounted, but may be at the contestant's option
- 3. Photographs must be packed properly to protect them during transportation
- 4. Non-winning entries will be returned only if sufficient postage is included when the prints are submitted
- 5. Each entry must have the following data written on the back of the print or mount Mame and address of contestant, type of camera, and film, enlarger and paper used
- 6. Contestants may submit no more than two prints in each group but may enter any or all groups
- e 7 Prints must be in black and white. Color photographs are not eligible
- 8. Prize-winning photographs will become the property of Scientific American, to be used in any manner at the discretion of the publisher
- 9 Scientific American reserves the right to purchase, at regular rates, any non-winning entry
- e 10. No entries will be considered from professional photographers
- 11 All entries in this contest must be in the hands of the judges by Dec-1, 1939 Results will be announced i issue dated Pebruary 1940
- 12 This contest i. open to all : photographers who are not in the employ of Scientific American

This Contest Closes Dec. 1, 1939-All Entries Must Then Be in Hands of Judges

is through the use of ink eradicator. This should be applied a little at a time, remo ing the line bit by bit. The black defect cannot be taken out all at once. For removing small black spots, another method is to use a small spotting brush molded to a fine point and tipped with white spotting color. The effect should be judged only after the color has been allowed to penetrate the paper at the treated point. If the result is too light, add a little gray after the first application has dried.

BATHING BEACH

IDEA

THIS suggestion is probably a little late THIS suggestion is provided, a con your for this year, unless you are on your way south, but it will keep until next time. "Stormy Weather Ahead," a low angle shot suggested by the darkening clouds, is a

"Stormy Weather Ahead"

subject that depends for its effect on the clouds, the nature of the lighting, and an exposure favoring the clouds. In this in-stance, the clouds covered the sun and an exposure made which was inadequate for the foreground figure, suitably rendered here in practically a silhouette. The shot was made as the subject swung slightly backward from the hips and looked up toward the approaching clouds.

LAST CALL .

DAST CALL.

The still time to enter the Fourth
Annual Scientific American Photography Conteat—but hurry, hurry:
Entries must be in the hands of the judges
by December I. Doll up your bost prints
so that they look their finest, for one of
them may bring you a valuable prine.
Full details of the contest appear on
this page. Be sure to read the rules carefully so that your prints will be eligible.

NARROW FORMATS

A PRINT does not necessarily have to a fall within the category of the regulation 5 by 7, 8 by 10 or any of the standard paper alzes. If the particular picture you have in hand looks better in a formst which is narrower with relation to its length than

"Make Money With Your Camera" **Photo-Markets**

SCHENTIFIC AMERICAN 24 West 40th Streft New York City the usual ratio, by all means go ahead and print it that way. In the subject illustrating this piece there seemed nothing to do but display of clouds is the principal attraction and their majesty is greatly emphasized by comparison of the towering masses with

"Majesty"

the small boats on the water below. The negative image had to be considerably "trimmed," but the effect and composition were greatly improved as a result.

IDENTIFYING PAPER

EMULSION SIDE

COME workers find difficulty while in the darkroom in telling the paper emulsion side from the uncoated side. This is particularly difficult with smooth paper. There are three general ways of telling the coated from the uncoated side. First, there is the familiar one of biting a corner of the paper. The side that sticks to the teeth is the emulsion side. The other telltale signs are that the emulsion side looks more shiny than the other and also that it has a tendency to curve in-ward, concave fashion.

WHAT'S NEW

In Photographic Equipment

If you are interested in any of the items described below, and cannot find them in our advertising columns or at your photographic dealer, we shall be glad to tell you where you can get item. Please accompany your request by a stemped emology.

Dozens of Illustration \$2.00 per Cop. Board Covers

JACOB DESCHIN, conductor of our "Camera Angles" department, will answer in these columns questions of general interest to ametic photographers. If an answer is desired by mail, enclose a stamped, addressed newdope, Queries should be specific, but Mr. Deckin cannot undertake to draw comparisons between monufactured products nor to advise on the purchase of equipment or materials.—The Editor.

Q. I have had some trouble with light leaking through the bellows of the camera. What is the proper method of testing for light leaks?— W. J. N.

A. One way is to remove the back of the camera, pall a high-proof cloth over the head and the camera and insert into the bellows a small 4-wolt lamp in a holder connected to a pocket lamp battery. Examen the bellows folds, joints and corners. If and when the source of the light leak is discovered, repairs may be made by filling the holes with rubber solution thickened with lamp black, powder, or the breaks or breaks may be covered with samp black powder, or the break or breaks may be covered with samp black powder, or the break or breaks may be covered with samp black powder, or the same process of black court planet.

Q. How can I obtain the letters A. R. P. S. after my name?—B. W.

A. These letters stand for Associate of the Royal Photographic Society of Great Britain) and are accorded to members of the Society who have achieved dustinction in some field of photography. Membership is open to all photography owhere in all parts of the world. The first step towards the acquasition of the covested letters is to fill out a regulation form and send it to the Secretary of the Society in London, accompanied with evidences of one's work. Periodical or the Society in London, and the secretary of the Society in London, which was the secretary of the Society in London, accompanied with evidences of our work.

Q. Where and how is distilled water obtainable?—M. J. R.

A. Distilled water may be purchased at the five-and-ten-cent store or at the drug atore. Water free of the foreign matter contained in water obtained from taps may be had by catching rain water in a non-metallic container, such as an enameled pail or crock.

Q. I wish to take stereoscopic color transparencies with a 35mm camera. I em acquainted with the Leica equipment for this purpose, but can you tell me of any other equipment for taking and viewing these pictures?— D.E.D.

A. You probably are aware that stereo pictures can be taken with any camera simply by using a still subject and shifting the position of the camera between the two expecures a distance of about 2½ inches appearation of the camera between the

two eyes of a human being. As for viewing the resulting stereos, any regular stereo viewer accommodating this size transparency will be suitable. An article on stereo photography appeared in our Camera Angles department in the November 1938 issue.

Q. I have had very little experience in photography and cannot appart much, but I will soon need an apparatus for use in plant-breeding work. Can you advise what type I must get for clear anapshots of plants and also photomicrographs of plant cells and the like?—A. L.

A. The least expensive outfits for your purposes are the Argus and the Mercury, for-both of which cameras special apparatus is available in these fields. The service departments of both these organizations will be glad to send you helpful data and suggestions.

Q. What do you think of taking two exposures on a single film without covering half of the lens? Will the pictures be sharp and worth enlarging?—L. D.

The Italian alogethe possible and is, in tact, an arrangement in regular use on vicetype cameras. A ground glass focusing-type camera is required and the proper negative masks must be provided so that one half of the film is covered while the other half is being exposed, and vice versas. If the focusing is accurately done there is no reason why both pictures on the same film should not be as sharp as one picture made on the

Q. Can you tell me where I can get a list of picture agencies?—J. C. A. Editor & Publisher, the newspaper

A. Editor & Publisher, the newspaperman's organ, has a complete list of syndicates that buy photographs. The list was reprinted some time ago in an issue of Camera Magazine, Philadelphia, Pennsylvania.

Q. Is it possible and practical to make sensitized paper for use in making photostatic copies of printed matter?—L. E. W.

A. Most hand sensitized papers do not have sufficient contrast for photostatic work. Rather, we would suggest the use of some such paper as Novasex or Outline Special.

SCIENCE TODAY AND TOMORROW

By Waldemar Kaemuffert

OVERING most of the especially inter-Cesting things in the gamut of the scientific and industrial world, Kaempffert, who never has learned how to be dull, entertains and painlessly informs the reader as he goes The sun, exploding stars, birth and death of the moon, life in the solar system; rocketing through space, explorers of the atmosphere, mystery of the atom, after coal, what?; the chemical revolution, can the laboratory create life?, evolution since Darwin; Carrel, man and his world, artificial lightning; speed; steamships; democracy and the machine—these are the headings under each of which the author. an outstanding interpreter of science, chooses to spill a myriad of significant scientific sidelights. Eminently fine reading for the man who doesn't want to study, yet wants to know what's going on around him. (275 pages, 5 by 8 inches, unillustrated) \$2 60 postpaid -A. G. 1.

STANDARD CHEMICAL AND TECHNICAL DICTIONARY

Ry H Bennett

IN the preparation of this dictionary, a definite attempt has apparently been made to produce a book which will be useful not only to chemists but also to those whose contacts with the profession are much more causal. In it will be found an explanation of the system behind the naming of organic chemicals, prefix names of organic chemicals, prefix names of organic of chemical since Since and or a single proper pronunciation of chemical single same of organic radicals, and a last giving the proper pronunciation to chemical names where the area of the control of the contro

THE BIRD, THE GUN, AND THE DOG By Ledyard Sands

BOTH masters and neophytes in the art of American game bird shooting will find this treatise on woodland and praine grouse, quall, pheasant, turkey, woodcock, snipe, rail, and waterfowl a vertiable encyclopedia of nimrodic information. Actually twelve books in one, the author's single volume covers every kind of American game.

bird from the smallest upland species to sea ducks and geese through the unique method of devoting in turn a division of each chapter to natural history of the bird, the satisfactory types of firearms for that particular genus, and the most adaptable dog for that form of hunting Reproducpaintings by Courtenay Brandreth, together with 18 other full page illustrations, in-crease enjoyment of the book A free, informal, narrative style presents the ornithological data, the technical advice on guns and various breeds of hunting dogs in a pleasing manner, all enlivened by episodes from the author's wide experience Major Charles S Askins, eminent firearms authority, wrote the foreword. (Complete index, glossary and bibliography, 494 pages, 7% by 101/2 inches.) -\$7.60 postpaid. De Luxe edition, 100 copies only, \$20 10 postpaid —A. D. R., IV.

MODERN PLASTICS, OCTOBER, 1939

It has been bound in an attractive stiff cover, the surface of which is a parquet of wood impregnated which is a parquet of wood impregnated to the surface of the plast should through the surface of the surf

FINDING NEW SUBJECTS FOR YOUR CAMERA

By Jacob Deschin

CAMERAS too often repose in closest and bureau drawers hecause their owners have exhausted their own limited resources of photographic subjects and have tired of repetition. With new visua opened to them through the ideas suggested by Mr. Deschin, they will find new joys, keen delights, in photographic exploration of hitherto unthought-of fields. The suggestions offered are far too great in number to attempt to list: they ower a wide range from city sidewskits to unusual models, from hobby photography to picture finding in the dark room. The best we can do here

is to say that this is one book which the ambitious amateur photographer cannot do without. (220 pages, 6 by 8½ inches, 24 excellent photographic illustrations, most of them full-page size.)—\$2.60 postpaid.— A. P. P.

SKEET AND HOW TO SHOOT IT By Bob Nichols

10 the skeet devotee this book will be a friendly, helpful critic in pointing out possible existing faults of form, stance, fit of gun, target lead, and other factors which may have tended to interfere with perfect scores. To the inexperienced skeet shooter it will be a complete and competent guide for the above named integers of the sport, as well as for choice of guns, constructive suggestions and extensive information on eyes and shooting glasses, clothing, field lay-out, and the entire game from station one to station eight. The author writes in clear, graphic style, gained from his own extensive experience in skeet shooting and from his knowledge and background as Arms, Ammunition, and Skeet Editor of Field and Stream. (177 pages, 6 by 914 inches, 46 illustrations)-\$3.60 postpaid -- A. D. R., IV.

THE STUFF WE'RE MADE OF By W. O Kermack and P. Eggleton

DIOCHEMISTRY is the central subject of this book, written by a staff member of the research laboratory of the Royal College of Physicans and a fecturer in biochemistry at the University, both of Edinburgh. It contains a very great amount of dependable data, some of it quite technical but all of it luckly explaned in elementary language and without pretense, centering around the efforts of science to understand the nature of life and its misterious processes. No better look by which the currous recesses, who better look by which the currous data of elementary backmanning the subject of the contract o

SCIENCE AND MECHANISATION IN LAND WARFARE By Donald Portway

APPROPRIATE now in the study of details of the war in Europe is the new volume for the first property of the work of the warding to find a warding or mechanization, ruleways in war, weather problems and stratesphere flight work of the Royal Engineers, the work of the Royal Corps of Signals, artillery survey, and war personnel. (158 pages, 5½ by 8% inches.)—\$2.50 postpaid—F. D. M.

We can supply our readers with any of the books reviewed in this department. Prices quoted include domestic postage. Foreign prices are necessarily higher due to increased shipping charges.

SCIENTIFIC AMERICAN, 24 West 40th Street, New York City

I enclose \$...... for which please forward at once books Nos.

A Monthly Department for the Amateur Telescope Maker

Conducted by ALBERT G. INGALLS

T long last, someone has actually built A Tlong last, someone has actually built the spectroscope and spectroheliograph (not to be confused with the spectrohelioscope) described in "ATM." third and fourth editions. For some reason this instrument never has been popular with the crowd. Arnold S. Mountfort, a portrait artist, 2200 Mountain Oak Drive, Hollywood, Calif., is the first maker (Figure 1). "The actual work took about two months of my spare time, mostly in London," Mountfort writes. "The recommended water clock driving mechanism ('ATM,' page 211)

was not a success, as it always went in jerks due to the darkslide's friction. Regarding the cost, about which you inquire, I cannot now state but, with a fair genius for getting material for nothing, the whole, including the coelostat, should not cost more than \$10 or \$12.

"The most difficult part was cutting and mounting the shts. By fixing the curved one on the end of a long piece of wood pivoted at the other end, I got a good and true edge by rubbing it against a piece of fine Car borundum stone for the male half and reversing them for the female. "It was all intensely interesting

and well worth the trouble. My first photographs were terrible tragedies The solar spectrum, though clear, was so over-exposed that it came out positive. But if there was nothing to work for it would not be half the fun. have found no need for the long focusing rods or for a shed, a galvanized cover giving sufficient protection."

Mountfort, at the time he wrote the above, was painting a portrait of R. W Porter to be contributed to a gallery of astronomers and telescope de signers of our time, "in order that those who will be working the 200-inch in 1000 years,' as Mountfort puts it, "may know something of the pioneers of this development of

FIRST big hurdle to jump when undertaking a Schmidt astronomical came has been the deep curve, otherwise a lot more Schmidts would be made by amateurs. The Lowers used 25 pounds of Carbo and played wet nurse to their grinding machine for 98 hours, in 1935, when roughing a deep f/1 curve out of a 12-inch Pyrex disk for a Schmidt. Today they use a Borium tool on a large lathe and do the job (to within ¼ inch of ultimate depth—as far as is safe) in one day. This is excellent-provided you have a Borium tool and a large lathe. The alternative — hand work — would require "less than a month," working union hours. Harold Lower states.

Fred Ferson, Biloxi, Mississippi, therefore aggested some months ago that an attemp he made to wangle the Corning Glass Works,

Corning, N. Y., makers of Pyrex baby bottles and 200-inch mirrors, into casting a batch of Schmidt blanks with approximate curve. Approached, Corning showed a co-operative spirit. "What size, what curve, would you like?" they asked. Offhand, one might reply casually, "Oh, all sizes, all curves." But this would make the disks cost real money, for the sale will not-cannot-be large. Ferson therefore suggested 12½ inches, 32-inch radius, as a mean-or, rather, mode. Lower agreed. So did others.

Figure 1: Mountfort and spectroheliograph

Advised," Corning stated that the most economical way for them to make these would be to rough grind the cavity rather than cast it in, as the molds are expensive; also, for some technical reason, to make the radius 36 inches. They found they could supply these at a little more than double the price of ordinary Pyrex disks of the same

Before announcing this fact it was thought best, however, to put these disks to actual test, so Corning sent Ferson a disk, 12½ inches, 36-inch radius, and he spit on his hands and went to bat with it. Final report: He spent 12 hours and used two pounds of Carbo in deepening the curve from 36 inches to 32 inches and truing it. Used convex tool of full diameter, which he cast from type metal. The soft metal ground away as fast as the glass: hence, no concave mate was needed. Metal tool also gave mute was needed. Metal tool also gave shallower pits, smoother surface, he states. In sum, he reported, it is now possible to grind and polish a primary for an //2 Schmidty by an //3 Wright, by hand, in about the time required for a mirror of like size but common focal length. For this, we may thank Ferson and Corning.

FAST month in this department it was i hinted that James G. Baker, of the Harvard College Observatory, had designed a family of flat-field cameras (Figure 2) equivalent in performance to the Schmidt. The following is his description of them:

"Many years ago Schwarzschild set out to find the most useful system of two mirrors possible. He found that, although there

exists a system that is aplanation and anastigmatic on a flat field, it is of no practical use because of the total silhouetting of one mirror by another. As a consequence, Schwarzschild reintroduced astigmatism and solved for the parametric equations of a family of aplanats with flat field. The bestknown member of the family is a system of two concave mirrors, the secondary being half the diameter of the primary. Astigmatism in the system limits the available field of this reflector.

"Improvements in the image quality of reflectors were of a minor nature until Schmidt introduced the idea that small deformations in an otherwise weak lens could be most effective in helping to eliminate the image defects of come and spherical aberration. Wright has generalized the original Schmidt camera into an entire family of Schmidt cameras and has shown that astigmatism cannot be eliminated on a flat field by correcting plate and one mirror alone. Wright's work in turn can be generalized to show that astigmatism cannot be eliminated on a flat field, even

when several correcting plates are employed, all separated, so long as the total powers of these correcting plates are of the second order with respect to the

"Three mirrors with aspherical surfaces can be designed to give excellent performande mathematically, but the silhouetting in such a system is hopeless. Thus, only one more possibility remains, and that is a system of one correcting plate and two mirrors. This combination produces a twoparameter family of telescopes with flat field. The two parameters remaining after all third order aberrations have been satisfied, are the distance of the correcting plate from the primary mirror and the distance of the photographic plate from the secondary mirror. When the correcting plate is placed immediately before the secondary, the tub length becomes extremely short compared with the focal length. For example, one combination produces a tube one sixth the length of the tube for a Schmidt of the same focal length and performance. For such a short tubb length all three of the curved optical surfaces are asphantical. The two

spherical mirror surfaces fortunately nos-

aspherical mirror surfaces sortunatery po-sess so infaction points.
"If the tube leagth be of no serious con-sideration, the two-parameter family in-cludes a remarkable one-parameter family with tube length about % that of the Schmidt of the same focal length, such that the two mirror surfaces depart inappreciably from spherical surfaces. The curve of the correcting plate becomes much more shallow, and is not much deeper than for the Schmidt of same focal length and aper-

"The reasons for the existence of the two-

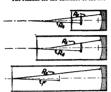

Figure 2: The Schmidt system compared with the two-mirror systems

parameter family can be seen from con-sideration of the Schmidt and Schwarzschild systems. Then, too, one can deduce the family from the Schmidt system. One starts by considering the usual Schmidt camera with an additional plane mirror secondary, untilted, so that the curved focal surface is inverted and near the primary. By keep ing the radial and tangential astigm surfaces coincident, and by variation of all the curves and separations, the curvature of field can be continuously reduced to the flat field here considered.

"Figure 2 shows an f/3 camera of short tube length with an 8 degree unvignetted field, also the corresponding camera of longer tube length and spherical mirror surfaces. Moreover, for comparison puroses a Schmidt camera of exactly the same light-gathering power, focal length, and un-vignetted field is shown. The apertures of the two-mirror systems have been adjusted to compensate for the additional silhouetting and extra surface, absent in the Schmidt.

The advantages that can be pointed out for the two-mirror system are the extremely short tube length possible, with consequent saving in space and material, convenience in loading the plate holder, and the existence of a large, flat, unvignetted field. To give an idea of the importance of the field. if the customary large paraboloidal reflector were converted into this type in the same tube, the number of square degrees phototube, the number or square degrees photo-graphed per night would equal the number of square degrees photographed by the para-boloidal form per month, the definition at the edge of the useful field being the same, from a very conservative calculation. For-tunately, the two mirrors and plate-holder are close together in what is usually the

stiffest part of the tube."
In Figure 2 the spherical surfaces, tange to the true surfaces of the mirrors in the shortest type, are shown dashed. The mirror curves are exaggerated to twice their true depths, the correcting plate surface many issues, and the fecal surface of the Schmidt

THE RECENTER'S CORNER

THE experienced telescope user is often less inclined to belittle the alt-azimuth type of mounting than is the beginner. With the equatorial type, because one axis is cocked over parallel to that of the Earth, it is necessary to keep moving the telescope tube in only one direction as the Earth rotates In the alt-azimuth, having the same axis perpendicular to the Earth's surfacethat is, at some angle to the Earth's axisit is constantly necessary to move the tube in two: for example, over a bit (azimuth) and up a bit (altitude). In practice this isn't nearly so much of a bother as it sounds; while the mounting is simpler to build The clean, trim all azimuth shown was built by J. L. Wagoner of Pittsburgh, Pa. It has a 6" mirror and a 7" aluminum tube The pillar is a piece of 4" brass tubing and the base and voke castings are of aluminum

TELESCOPTICS

(Continued from preceding page)

IN the Journal of Scientific Instruments
(London), August 1939, H. W. Cox. 47 Upper Green, Mitcham, Surrey, England, an amateur whose first Schmidts were described in the February number, describes in a six-page article his technic of making Schmidts. He sent us an extra copy of the article, which will be lent to those seriously doing Schmidt work who wish to ask for it, provided they will promise to return it promptly so that it may be passed on to others Cox will also send copies to genuine Schmidt workers, if asked. The paper would mean little or nothing to others, as the methods are in no way applicable to work on ordinary telescopes; Schmidts being advanced work.

ONCE a year a "nova" breaks out among telescope makers: verses Most recent poet is the proprietor of the Apex Monument Works (gravestones!), 6815 West 27th Ave., Edgewater (Denver suburb), Colo., who offers the following outburst (novae are due to an overproduction of energy);

The Amateur Mirror Maker By Anton Bohm

He walks at night, around a keg, on top a disk of glass. He pushes forth and pulls it back—another piece of glass. For months and months he's kept it up, his patience still intect still intect ne hundred miles he's surely walked around that circular track

He counts the minutes and the strokes, elliptical and straight the fights against a turned down edge and spheroids much oblate much oblate
aboloid, hyperboloid, ATMA, TH...
words and terms that he can use with plira-

And every now and then he takes his pretty, shiny disk—

With loving care he handles it, indeed he takes no risk no risk---And puts it on a testing stand to see what he can see,
And squints along a rangr blade and then he shouts
with size:

"At last; I see what seems to be a doughnut fat and round!" But though the shape is there siright, the depth is too profound.

The distance from the inner sone, compared with from the rim, Is much too far away as yet So it appears to him

Again the weary grind begins It surely is no cinch. The surface must be right within one millionth of an inch. One millionth on a ninch promptly sak "How does he know when he is done with his gigantic task?"

His pinhole lamp and razor blade—they will reveal to him.

The mirror in its perfect shape, correct from rim The mirror in its perfect shape, correct from rim to rim But if you knew the grief he has with rings de-pressed and raised, With turned-down edge and edge turned up, you'd surely be amazed

But that is not the only grief-experience he must gain
It's finding scratches, sleeks and pits that causes
him much pain
Dust is a thing that he abhors—he flies into a tentrum

When finding on his polished disk a grain of

Carpowndan

"Oh Wifey! Did you sweep the floor?" he hollers from his shop "If you insist on cleaning up, I'll surely buy a lock." "Indeed you'll not," replies his spouse, "I never yet have seen a place so groy, it's a fright—I'll never get it clean "Rouge over every thing I see It surely is a mess Rouge on my towels, yes on the walls. It's even on my dress"
But all hard tasks come to an end some night the Foucaut test
Will throw upon his speculum the shadow he loves best.

The shape is there—the depth is right, at last the thing is done.

By heaves a sigh of deep relief—some people call it fun. - it fun
And so will you, I dare predict Soms day you'll
see it—but
You never will, till you've become a Telescoptic Nut.

FORKS, if made by casting from carefully I shaped patterns, may be made very pleasing to the eye but, if not, they sometimes fail to satisfy the telescope maker's feeling for beauty. A kind of fork that can be made with a lathe alone, yet which is pleasing to the eye, is shown in Figure 3. Otto C. Ramussen, 57 Brunswick Ave., Troy, N. Y., designed this fork, in which he used 1½" steel shafting, a circular plate of ½" steel and underneath it, two rollers. The telescope, a 6" of 50" f. is. concern. The tenescope, a or of 20° 1. %, or of souther than the control of the control of the control of angle iron with a 1/4" steel deck. On

Figure 3: Rusmussen's neat fork

this deck are two double glasses and at the apices three leveling screws with locknuts. The hour circle is of the floating type. The square tube is made of 1/2" x 1/2" x 1/3" angle iron with diagonals of 5%" x 1/3" strip steel

Rasmussen also made a nocturnal or horometer (Figure 4) for giving sidereal time. The handle is held perpendicularly, Polaris is sighted through the central hole and the straightedge is turned to line up on Beta Ursa Minoris. The pointer then shows sidereal time within about 5 minutes

BOTH "ATM" and "ATMA" recently underwent minor operations when exhaustion of stocks led to reprintings (notenot new editions). Misprints were corrected and in "ATM" a few changes made. Old note on p 333 discouraged refractor work, new one encourages itthings have progressed Note on p. 458 was replaced by one telling why photographic lens making is highly advanced work, because numerous novices seem to get the idea that making a photographic lens would be a "simple introduction" to telescoptics! Hallucination.

TRADE MARKS

AND

UNFAIR COMPETITION

By ORSON D. MUNN

A Trade Mank is an intangible asset of a business, yet its actual value may grow so large that it becomes the very foundation on which depends the whole structure of the business. Because of this fact, every business man should have available such information on trade marks as will enable him to judge with a fair degree of accuracy the desirability of any mark which he may be considering.

Here, in one handy volume, written in non-legal terms, is a simple yet comprehensive interpretation of the Federal statutes and the body of common law relating to trade marks and unfair competition.

Price \$1.00 postpaid

(The Edutor will appreciate it if you will mention Scientific American when writing for any of the publications listed below.)

ENGINEERING: A PROFESSION, edited by J. Anderson Ashburn, is a 25-page booklet dealing specifically with the functional aspects of engineering. It should be of great assessance to students who, having decided to follow engineering as a life work, are still at a loss as to what particular vork, are still at a loss as to what particular election. The Wirkson Technic, College of Engineering, University of Michigan— 25 cents.

THE SHOOTEM'S BILLE, 1940 edition, is a 512-page called that illustrates and describes 16,000 items covering guns, accessres, gun took, ammunition, and all the other gadgets dear to the heart of the gun hobbyist. Thus one book might almost be called the equivalent of a whole gun library ance? it can serve as a gunde to practically everything in which the reader would be interested. Stoget Arms Corporation, 307 Fifth Avenue at 42nd Street, New York, NIV York—310.00

Konacamom. Protognaper in Colon, is a 52-page hooklet which discusses Kodachrome film, and gives data on its use for
full-color filming. Exposure technique technique
both in daylight and artificial light is
trated, and advice on using a photoelectric
exposure meter is included. A number of
the illustrations are in color. Eastman
Koduk Company, Rochester, New York.—
25 cents.

THE BROWNING PRESELECTOR AND VISUAL FREQUENCY MONTOR IS a snale page leaflet, Bulletin 103A, which describes two instruments of great value to the serious anateur radio operator. The preselector described has a general coverage of 5 to 185 meters, with electrical band spread, and gree 25 to 70 BB gain on all Bands. The visual frequency monitor insures precise frequency measurement on the anisateur bands. Browning Laboratories Incorporated, Winchester, Measuchastett.—Create.

STATISTICS OF RATEWAYS OF CLASS I, is a 12 sheet folded bulletin based on the official summaries of the Interestate Commerce Commission from 1950 to 1938. It covers—among other phases—investment and income, fixed charges and dividends, or the covers—among other phases—investment and income, fixed charges and income, fixed charges and services, and income, fixed charges are consistent of the commission of

AO PROPEZ is a 26-page booklet which gives a comprehensive picture of the world's clotest and largest optical institution and of the people who work for it. Well-libustrated, the booklet was created by American Optical Company for distribution to prospective employees, company visitors, editors, and the general public. Although the booklet can be read in a few minutes, the reader will nevertheless get

as accurate idea of the cushtion behingthen optical concern and its worker's sign alian as understanding of the introate includes problems involved in the manufacture of optical optigment of all kinds. The brookle can be considered a valuable contribution to the art of establishing cortial relationships between industry and the public and as such may well be worth studying. American Confession Company, Scalabridge, Mess.

LEITZ BOOKLET No. 7838 describes the Leitz Gnome II home projector for two by two-inch slides and gives complete information on the projector and accessories. E. Leitz, Inc., 730 Fifth Avenue, New York, N. Y.—Gratis.

SOME CRAMIC MANUACTURING DEVELOP-MINTS OF THE WISTRIME ELECTRIC COM-PANY, by A. G. Johnson and L. I. Shaw, is a 25-page illustrated report which gives a general picture of the development work introved in the introduction of manufacturing processes for various ceramics as used in telephone apparatus. The work reported here should be of interest to many other modustral fields. Bell Telephone Laboratones, 463 Feas Street, New York City— Limited free distribution.

BLASTING DTCLES WITH EXPLOSUES IS a \$\hat{E}_{2}^{2} page illustrated booklet designed to give its readers a working knowledge of the use of dynamics for this particular purpose. The information applies specifically of construction, and for other purposes where continuation and for other purposes where continuation and for other purposes where tures. Desides the detailed instruction so that the continuation of the source, safety rules and practices, and so on. \$\hat{E}_{1}^{2} due Pont of Nemours & Company, far \$\hat{E}_{2}^{2} (Minington, Delaware—Grafist.

Allis-CHALMERS TEXPORE DRIVES AND Lo-MAINTENANCE MOTORS is a 28-page illutrated catalog that shows various types of industrial drives and gives data on how a drive should be selected for a particular purpose. It also lists various types of elotric motors which are particularly adaptable to varying operating conditions. Allis-Chalmers, Mikouskee, Wisconsin.—Gratik

Earty Fise-Marking Merrisons and Devices, by Warren N. Watson, B.S., A.M., is an interesting book of 71 pages plus an index which gives a running story of the whole history of fire-making from the most primitive implements of early man and more modern but undrillised races down to the present day match. Historical and described are five drills of varieties and primiting of the primiting of the primiting and physical methods, including the five pieton. Farren N. Fetton, Edvins, Virginis.— 150 cloth, 1200 paper.

KORAN FILMS in a 56-page booklet on Koeks rull films, filmpacks, ministures and short films. Photographic characteristics of the films, such as speed, contrast, and the libs, are described, and the essentiment of terms are described, and the essentiment of terms are explained. Of especial value in film information as so the photographic provides full information as on the photographic provides full information and speed of each film. Essenten Kodel Senten.

LEGAL HIGHLIGHTS

Patent, Trade Mark, and Related Legal Proceedings That May Have a Direct Effect on Your Business

By ORSON D. MUNN, Litt.B., L.L.B., Sc.D.

New York Bar Editor, Scientific American

UNDRAMATIC

A SET of rules is not a dramatic theme er the copyright laws. This principle is illustrated by a suit for copyright infringement, brought by the author of a book relating to sales arguments, against a prominent automobile manufacturer. It was charged by the author that the copyright on his book was infringed by a moving picture used by the automobile manufacturer for demonstrating proper sales tech-nique to its salesmen. The portion of the book which was alleged to be infringed contained a list of six principles or rules of persuasion to be followed in presenting a sales argument. The accused moving pi ture film depicted three salesmen, two whom expounded and demonstrated faulty sales arguments. The third salesman expounded and illustrated the proper sales approach and correct sales arguments. In the course of his portrayal the salesman listed certain rules or principles to be followed in presenting a sales argument and the rules thus expounded in the moving picture were similar both in content and in sequence to the six rules listed in the In illustrating the proper sales approach the third salesman carried out or followed the rules which he expounded It was contended by the author of the book that because of the listing of the rules or principles of salesmanship as set forth above and because of their portrayal in the manner described, the moving picture constituted a dramatization of the book and accordingly was an infringement of the copyright thereon.

The Court rejected this contention, pointing out first of all that "a set of rules is not a dramatic theme" and that accordingly the moving picture could not be considered a dramatization of the book.

SELLER BEWARE

TME seller of a patent should beware that he gloss not infringe it because in a suit for infringement of the patent he as the patent he cannot defend on the grounds that the patent is invalid. In a recent suit for patent infragments the inventor of a box for paper rolls had been an officer of the plantiff deepvarion and while in its employ had assigned his patent to the corporation. Subsequently, he served his connection with the plaintiff corporation and organised the defendant corporation for the purpose of manufacturing and selling, boxes paper solls. Thereafter the plaintiff importation sued both the inventor and the fendant corporation, charging patent laringspinent and one of the defenses ratiosed where the substitution of the content was turtiled. The Court was that the patent was turtiled. The Court

ruled that the defense of invalidity could not be rassed because of the previous relationship between the inventor and the plantific corporation and because of the minimate connection between the inventor. This suttains and the defendant corporation. This suttains and the defendant corporation. This suttains and the previous control of a patent cannot subsequently question the validity of the patent in a suit brought by the assignee but also for a carries it one step further and holds that a corporation organized and controlled by the assigner cannot question the validity of the patent.

LACQUER

A PATENT on lacquer consisting of a combination of nitrocellulose and a particular synthetic resin was held valid and infringed in a recent suit for patent infringement which illustrates that the sub stitution of one ingredient for another may amount to invention. The particular synthetic resin which was mixed with the nitrocellulose was described in the patent as a solution of a glycerol ester of a resin and organic carboxylic acid selected from the group consisting of phthalic, maleic, fumaric, malic, and succinic acids. The Court found that prior to the patent in suit lacquers had been made by mixing nitrocellulose with other types of resin. The Court also found that the particular resin described above was known and had been used for other purposes prior to the patent in suit. It was argued by the defendant that the mere substitution of one resun for another did not amount to invention but was within the range of routine laboratory work and represented mere mechanical On the basis of the evidence introduced in the case, however, the Court concluded that the results obtainable by mixing reams with nitrocellulose could not be predicted, that the production of the lacquer covered by the patent in suit resulted from considerable experiment, and that the lacquer was superior to the lacquers of the prior art. As a result the Court held the patent to be valid.

WEATHER STRIPPING

A PATENT for an all-metal weather without the use of an all-metal water points which is applied to the window without the use of anis, screws, or other extraurous fastening means was used to the control to the patent in suit disclosed a weather stripping formed of a unitary metal clamping portion adapted to clamp to either the sash or the frame and a resilient metal yeather classing strip attached to the class provides. The demants meantened with the classification of the weather than the control to the class of the cla

stripping having a metal clamping portion and a resilient weather closing strip. However, the defendant's weather stripping differed from the weather stripping shown in the patent in several respects and it was con tended by the defendant that because of these differences his stripping did not infringe the patent. Thus, in the stripping shown in the patent the clamp was formed with an arcuste hooked portion which was not embodied in the defendant's structure. The Court found that plaintiff's weather stripping was new and represented a substantial advance in the art. As a result it concluded that the differences referred to by the defendant were not important and did not avoid infringment.

OUTSMARTED

A RECENT case in the New York State
A Supreme Court involved a rather
ovel application of the so-called Far Trade
Act. The Fair Trade Act which has been
noted of the states of the Union permits a
manufacturer to enter into contracts with
no sustomers, fraing the retail prices at
which they may sell commodities bearing
his trade mark, anne, or brand and provides
that knowingly selling commodities bearing
they commodities bearing
the trade mark, after constitution unifar com-

In the case in question a silk manufacturer entered into a contract with a dress man facturer confining the sale of silk bearing the trade mark "Pussy Willow" in the cutting trade to the dress manufacturer who in turn agreed that the retail price of the dresses made from the "Pussy Willow" fabric should not be less than \$12.95. A prominent New York department store attempted to purchase dresses made from the "Pussy Willow" fabric from the dress manufacturer but since the department store would not agree to refrain from selling the dresses for less than \$12.95 each, the dress manufacturer refused to sell the dresses to the department store. Thereafter, the department store obtained dresses from another and unauthorized source but which were nevertheless manufactured from genuine "Pussy Willow" fabric and they proceeded to sell the dresses for less than \$12.95 each. The silk and dress manufacturers then sought to obtain an injunction against the department store on the grounds that the sale of the dresses for less than \$12.95 each was in violation of the Fair Trade Act and constituted unfair competi-

The Court refused to grant the injurction, pointing out that the dress was manufactured by some other source and was not a product of the dress manufacturer nor did it bear his trade mark, name, or brand. The Court also pointed out that, while the allk was undoubtedly the product of the allk mass undoubtedly the product of was immunifacturer, the dress did not constitute a "commodity" produced or owned by ing that every a constitute undark competition, made the following statements.

"Obviously, the defendant outsmarted the plaintiffs. But the law does not essay to reach every case of outsmarting; nor does every case of outsmarting; nor does every case of outsmarting constitute unfair competition. I recognize the plaintiff's embarrassment and possible loss. But I am unable to perceive that the law here invoked afforcis them relief."

Are You-

e of the many who are king a new field to en-

seeking a means to save money wherever possible?

If you are, here is a practical solution to your problem.

HOPKINS' CYCLOPEDIA OF **FORMULAS**

Is the foundation for the beginning of a fascinating hobby; the groundwork on which to build a practical knowledge of useful chemical facts.

Is the foundation for hundreds of suggestions for those who are seeking salable articles which can be manufactured at home profitably on a small scale.

TF you want to save money on wines and liquors; your dyes, inks, polishes, soaps, paints and varnishes. adhesives, antiseptics, bleaches, cosmetics, etc.

You can profitably make them from the 15000 formulas contained in the 1077 pages of

HOPKINS'

Cyclopedia of Formulas \$5.50 postpaid (domestic)
